ADVERTISEMENTS.

We require that every advertiser satisfy us of responsibility and intention to do all that he agrees, and that his goods are really worth the price asked for them. Patent-medicine advertisements, and others of a like nature, can not be inserted at any price.

Rates for Advertisements.

All advertisements will be inserted at the rate of 20 cents per line, Nonpareil space, each insertion; 12 lines of Nonpareil space make 1 inch. Discounts will be made as follows:

On 10 lines and upward, 3 insertions, 5 per cent; 6 insertions, 10 per cent; 9 insertions, 15 per cent; 12 insertions, 20 per cent; 24 insertions, 25 per cent.

On 50 lines (½ column) and upward, 1 insertion, 5 per cent; 3 insertions, 10 per cent; 6 insertions, 15 per cent; 9 insertions, 20 per cent; 12 insertions, 25 per cent; 24 insertions, 33½ per cent.

On 100 lines (whole column) and upward, 1 insertion, 10 per cent; 3 insertions, 15 per cent; 6 insertions, 20 per cent; 9 insertions, 25 per cent; 12 insertions, 33½ per cent; 24 insertions, 40 per cent.

On 200 lines (whole page), 1 insertion, 15 per cent; 3 insertions, 20 per cent; 6 insertions, 25 per cent; 9 insertions, 30 per cent; 12 insertions, 40 per cent; 24 insertions, 50 per cent.

An additional discount of 10 per cent, where *electro-types* are furnished. A. I. ROOT.

CLUBBING LIST.

We will send GLEANINGS—
With the American Bee-Journal, W'y (\$1.00) \$1.75
With the Bee-keepers' Magazine, (25) 1.25
With the Canadian Bee-Journal, W'y (1.00) 1.80
With all of the above journals, 3.25

[Above Rates include all Postage in U. S. and Canada.]

Untested Queens Ready to Mail ALL WINTER LONG.

I have now on hand untested queens ready to send out by first mail. In regard to my responsibility, I would refer you to A. I. Root, with whom I received instruction in bee culture. The friends who order these queens during the winter time are expected to have sufficient experience to take care of them when they are received at the postoffice. In the Southern States, where the winters are so mild the bees can fly almost all winter long, of course there will be little more difficulty in receiving them in the winter months than at any other time.

N. ADAMS,
Sorrento, Orange Co., Fla.

A Complete Business Outfit.

I have for sale two 8x12 printing-presses—one of them foot-power; 50 fonts of type, many of them full printer's fonts; regular cases, leads, furniture, etc., sufficient to do a large job-printing business. Cost me about \$300. I offer the whole for \$125, having other business to take my time.

W. EARLE CASS,
Roseland, Essex Co., N. J.

FLAT - BOTTOM COMB FOUNDATION.

High side-walls, 4 to 14 square feet to the pound. Circular and samples free.

J. VAN DEUSEN & SONS.

5ftd Sole Manufacturers,
SPROUT BROOK, MONT. CO., N. Y.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or \$2.00 per annum, when given once a month, or \$4.00 per year if given in every issue.

\$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or \$2.00 per year.

Those whose names appear below agree to furnish Italian queens for \$1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for \$1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

CONVENTION NOTICES.

The next meeting of the Sheboygan Co., Wis., Bee-Keepers' Society, will be held at Hingham, Jan. 13, 1887. MRS. H. HILLS.

The bee-keepers of the western part of Ontario, Canada, will hold a convention at Tilbury Center, Jan. 12 and 13, 1887. All are invited to attend. N. SMITH, Sec.

The Annual Convention of the Vermont Bee-Keepers' Association will be held at the Van Ness House, Burlington, Vt., on January 13th and 14th, 1887. A cordial invitation is extended to all, both ladies and gentlemen. R. H. HOLMES, Sec., Shoreham, Vt.

The Ohio Bee-Keepers' Association will hold their annual convention January 11, 12, and 13, 1887, in the parlors of the Farmers' Hotel at Columbus, Ohio, where good accommodations can be had at \$1.00 per day. You are requested to see on hand. C. M. KINGSBURY, Sec.

The Nebraska State Bee-Keepers' Union will hold their next annual Convention at the Red Ribbon Hall, Lincoln, Neb., commencing January 12th, 1887, at 1:30 P. M., and continue three days. All persons interested in the culture of bees and sale of honey are requested to be present. For full particulars address H. N. PATTERSON, Sec., Humboldt, Neb.

The Northeastern Ohio, Northern Pennsylvania, and Western New York Bee-Keepers' Association will hold its eighth annual convention in Chapman's Opera House, Andover, Ohio, on Wednesday and Thursday, January 19th and 20th. First-class hotel accommodations at \$1.00 per day to those attending the convention. A general invitation is extended to all. M. E. MASON, Andover, O., C. H. COON, New Lyme, O., Acting Sec. Pres.

The 18th Annual Convention of the New York State Bee-Keepers' Association (formerly the Northeastern), will be held at Agricultural Hall, Albany, N. Y., January 11, 12, and 13, 1887. GEO. H. KNICKERBOCKER, Sec.

PROGRAMME.

FIRST DAY.—TUESDAY, JANUARY 11TH.

Called to order at 2 P. M.—Reading the minutes of last meeting.—Receiving members and collecting dues.—Reports of Secretary, Treasurer, and Standing Committee.

DISCUSSION.—Alsike Clover as a Honey-plant, and its Relative Value to Other Clovers as Feed for Stock: Led by C. M. Goodspeed, Thorn Hill, N. Y.—DISCOURSE on the Chapman Honey-Plant, by H. Chapman, Versailles, N. Y.

EVENING SESSION, 7 P. M.

DISCUSSION.—Rendering Old Comb into Wax: Led by Ira Barber.—ESSAYS.—EXTENDED HONEY: Its Relative Value in Comb Honey, by Dadant & Son, Hamilton, Ill.—The Middleman in the Wholesale Market, by C. F. Muth, Cincinnati, O.

SECOND DAY.—WEDNESDAY, JANUARY 12TH.

Called to order at 9 A. M.—Receiving Members.—Appointment of Committees.

DISCUSSIONS.—1. Cause of the Late Depression of the Honey-Market: Led by L. C. Root, Mohawk, N. Y.—2. Bee-keeping by Women, as an Occupation: Led by Mrs. L. M. Thomas, Tacony, Pa.—3. Bee-Journals and the Supply Trade: Led by John Aspinwall, Barrytown, N. Y.

AFTERNOON SESSION, 1 P. M.

Receiving New Members.—Election of Officers.—President's Annual Address.

DISCUSSION.—1. Scientific Ventilation of Bees in Winter Repositories: Led by P. H. Ellwood, Starkville, N. Y.—2. Overstocking the Honey Market: Led by Capt. J. E. Hetherington, Cherry Valley, N. Y.—Discussion of questions from Question-Box.

EVENING SESSION, 7 P. M.

DISCUSSIONS.—1. The Outlook of Bee-keeping in the Future: Led by A. E. Manum, Bristol, Vt.—2. Foreign Honey for North America: Led by S. T. Pettit, of Canada.—Discussion of special questions handed in by members.

THIRD DAY.—THURSDAY, JANUARY 13TH.

MORNING SESSION, 9 A. M.

DISCUSSIONS.—1. Conventions as a Means of Promoting the Financial Welfare of the Bee-keepers: Led by essay from Jas. Heddon, Dowagiac, Mich.—2. SEPARATORS: Led by N. N. Betzinger, Marcellus, N. Y.—3. Bee-keeping as a Science: Led by Arthur Todd, Phila., Pa.—Answering questions from the Box.

AFTERNOON SESSION, 1 P. M.

DISCUSSIONS.—1. The Advantages and Disadvantages of Patent-Rights to Bee-keepers: Led by G. M. Doolittle, Borodino, N. Y.—2. The Bee-hive for the Future: Led by R. F. Holtermann, of Canada.

Reports of Committees.—Miscellaneous Business.—Adjournment.

The Headquarters of the Convention will be at the Globe Hotel, State St., Corner Pearl. Board \$2.00 per day.—Board at the Kimball House, No. 69 Washington Ave., \$1.00 per day.

Persons desiring to secure board will please write to John Aspinwall, Barrytown, N. Y., who has the matter in charge.

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 5 lines, and you must say where you want your ad in the department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. Of course, this department is intended only for bona-fide exchanges.

WANTED.—To exchange for cash, or good horses and mules, 200 colonies of bees in Simplicity frames; also 40 acres of land adjoining the city. 20tfdb ANTHONY OPP, Helena, Phillips Co., Ark.

I HAVE about 5 lbs. of spider-plant seed. I will exchange the same for different kinds of flower-seed or plants of any sort that are useful and ornamental. J. W. ROSS, 23-24-1-2d Phair, Brazoria Co., Texas.

WANTED.—A foundation-mill, or offers, for a first-class incubator—been used three seasons. 23tfdb D. S. HALL, So. Cabot, Vt.

WANTED.—To exchange 8 vols. "Campaigns of the Civil War" (new) for a good bracket saw or turning-lathe. J. S. MASON, Medina, O.

WANTED.—To exchange nursery stock of all kinds (evergreens a specialty) for pure Italian bees, queens, 2 or 3 frame nuclei, fdn., apiary supplies of all kinds, seedling basswood-trees, a trio of White Leghorn fowls, alsike clover seed. When making inquiries, please give price of your goods. My price list free on application. R. A. LEWIS, Cherokee, Iowa.

THOROUGHbred fowls, Brown Leghorns, S. S. Hamburgs, W. C. B. Polish, P. Rocks and Wyandottes, Bonney's, Forbes', Hawkins', Wilcox & Fultz' strains. We will sell for cash, or exchange for fdn. and beeswax. Price list free. 18-19tfdb A. H. DUFF, Creighton, Ohio.

WANTED to exchange or sell, a Given fdn. press, 3 tanks, and ½ doz. dipping-boards. 1tfdb J. SWALLOW, 2816 Mo. Ave., St. Louis, Mo.

WANTED to exchange, S. B. Leghorns and S. S. Hamburg cocks for comb foundation, or \$1.00 cash; \$2.00 per pair. Address 1-2d L. C. CALVERT, Poplar Flat, Lewis Co., Ky.

HOW TO RAISE COMB HONEY.

Price 5c. You need this pamphlet, and my free bee and supply circular. 18tfdb OLIVER FOSTER, Mt. Vernon, Linn Co., Iowa.

IMPORTED QUEENS.

In April.....	11 francs in gold.
May and June.....	10 " " "
July and August.....	9 " " "
September and October.....	7 " " "

No orders received for less than 8 queens. Queens which die in transit will be replaced only if sent back in a letter. CHARLES BIANCONINI & Co., 1-11d Bologna, Italy.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

Seeds for the Garden and Greenhouse for 1887.

As a number of the friends in the South are now sending in their orders for seeds, it reminds us that it is time to indicate our preferences, and to let you know what we feel like advising and offering for sale the coming year.

PRICE 5 CTS. PER PAPER; 10 PAPERS, 40 CTS.; 100 PAPERS, \$3.50.

Seeds of new or rare vegetables and novelties, we include at the uniform price of 5 cents per package; but, of course, we are obliged to put a smaller number of seeds into such packages. This will be noticed with the *White-Plume Celery* and *Snowball Cauliflower*, etc. Now, these 5-cent papers are all sent by mail postpaid; but when you order seeds BY THE OUNCE OR POUND, you must pay 2c extra for postage and packing on each and every ounce, and 18c extra for postage and packing on each and every pound of seeds ordered. You will notice from this, that the FIVE-CENT PACKETS, POSTPAID BY MAIL, never contain a FULL OUNCE of any thing.

BEANS.

Landreth's First in the Market. Pt. 20c; pk. \$3.00. The earliest shell beans.

Dwarf German Wax, or Butter Beans. Pt. 10c; pk. \$1.50. The earliest snap-short variety.

Golden Wax. Pt. 10c; pk. \$1.50.

A staple snap-short bean.

Southern Prolific. Pt. 15c; pk. \$2.25.

The best snap-short pole bean, maturing in 70 days.

Large Lima. Pt. 15c; pk. \$2.00.

The above beans will be furnished in 5-cent packages; but where they are to go by mail, postpaid, of course the above packages will have to be quite small. If wanted by mail, add 15c per pint for postage.

BEETS.

Eclipse. Oz. 10c; lb. 75c.

This gave us the best satisfaction last season of any thing we ever raised in the way of beets. They are a very quick grower, of excellent quality, and the appearance of the bright smooth scarlet bulbs is fully equal to any thing that has been pictured in the colored plates of our catalogues. In order to get a fancy price for them, start them in the greenhouse, and transplant when of the size of peas, or a little larger. They bear transplanting well, and are exceedingly hardy.

Philadelphia Turnip. Oz. 5c; lb. 50c.

This is a little later and larger than the above, and is a novelty because of its alternate rings of dark and light pink.

Long Blood Red. Oz. 5c; lb. 50c.

An old standard variety.

CABBAGE.

Select, Very Early Jersey Wakefield.

Oz. 25c; lb. \$3.00.

Our cabbage seed this year is raised by Francis Brill. At the Experimental College Farm, at Columbus, O., they give his cabbage seed the preference over that raised by any other seedsmen, and they have tested nearly all of them. They all say that the Early Jersey Wakefield, of their best selected strain, is fully as early as any other cabbage known, and greatly superior in quality. We sold single heads last season at retail at 30c each, raised from plants started in the greenhouse in February.

Henderson's Early Summer. Oz. 25c; lb. \$3.00.

This comes next to the Jersey Wakefield; and although it is an early cabbage, under very favorable conditions it produces large heads of most excellent quality.

Winningsstadt. Oz. 10c; lb. \$1.50.

Much like the Jersey Wakefield, but later and larger. The heads are round, and some of them are so hard as to seem almost like bullets. Our customers of last season greatly preferred these and Henderson's Early Summer cabbage to the later flat cabbages.

Flat Dutch. Oz. 10c; lb. \$1.50.

This is a standard late cabbage, for winter.

Stone Mason. Oz. 15c; lb. \$2.25.

Another standard variety, but, as its name implies, it produces harder heads than the Flat Dutch.

Perfection Drumhead Savoy. Oz. 10c; lb. \$1.50.

The Savoy cabbage is handsome in appearance, and richer and finer in quality, than any of the other varieties. In taste it nearly approaches the cauliflower.

Large Red Drumhead. Oz. 10c; lb. \$1.50.

This is a red cabbage for pickling. The bright red, by way of contrast, will make a load or lot of cabbages attract attention, and there is always more or less demand for red cabbage for pickles.

CARROTS.

Orange Danvers, Half-Long. Oz. 5c; lb. 60c.

CAULIFLOWER.

Brill's Early Snowball. $\frac{1}{4}$ Oz. \$1.00; oz. \$3.00.

Nice specimens of early cauliflower often bring extravagant prices, and it pays well to start them in the greenhouse, and use hand-glasses to forward them before the hot weather comes on.

CELERY.

Henderson's White Plume. $\frac{1}{4}$ Oz. 15c; oz. 50.

We place this at the head of the list, and especially for early celery. During the past season we had fine stalks on the market in July, and it sold readily at 10c each. We are planning to have celery this year in the market in the month of June. The seed was started in the greenhouse about the middle of December. On account of its self-bleaching qualities it is better fitted for early celery than any other.

Golden Dwarf. Oz. 20c; lb. \$2.50.

One of the standard sorts for a later crop. The golden tint of the head stalks makes it a very handsome vegetable.

Boston Market. Oz. 20c; lb. \$2.50.

An old standard variety in and around Boston, and raised largely throughout the land.

Major Clark's Pink. Oz. 25c; lb. \$3.00.

While the White Plume is the earliest and finest in appearance, we regard the above as the richest and most toothsome of all the celeries. It also, under favorable circumstances, makes exceedingly rapid growth. Plants set in September, the past season, made stalks weighing 2 lbs. each, by the middle of November.

CORN (FOR TABLE USE).

Ford's Early Sweet.

We put this at the head of the list on account of its excellent quality and exceeding earliness.

Crosby's Extra Early.

This is a great yielder, with soil suitable, although it comes a little later than Ford's.

Extra Early Minnesota.

One of the standard sorts.

Late Mammoth Sugar.

This is excellent in quality, and gives ears of mammoth size, and is a wonderful yielder. Our trade has been so large in this kind of corn for eight or ten years past, that we have now thirty or forty bushels dried on the husks by steam heat.

Corn we sell at 5 cents for a half-pint package; but at this price purchasers must pay the postage, which is 7 cents for each half-pint. If wanted in larger quantities the price will be \$1.00 per peck, or \$3.50 per bushel.

CRESS, OR PEPPER GRASS.

Extra Curled. Oz. 5c; lb. 50c.

CUCUMBER.

Early Frame. Oz. 5c; lb. 50c.

The earliest cucumber.

Rawson's Improved Early White Spine.

Oz. 50c; lb. \$3.00.

This is the kind he uses for raising in his greenhouse, and the cucumbers bring 50 to 75 cents each, even where he raises them by the thousands. Fine specimens are wonderfully handsome, and taking, and they sometimes grow to a great size without getting yellow.

Short Prolific Pickle. Oz. 10c; lb. \$1.00.

This is the kind generally used for raising pickles for market.

KOHLRABI.

White Vienna. Oz. 20c; lb. \$2.50.

This is a quick-growing vegetable, half way between turnip and cabbage. If the plants are started in the greenhouse, the vegetable may be put on the market at the same time with the very earliest cabbages; and where people once get a taste of it, it is pretty sure to meet with a rapid sale at good prices.

LETTUCE.

Landreth's Forcing. Oz. 40c; lb. \$5.00.

Excellent for hot-beds and cold-frames; exceedingly early. The heads are small, and may be sent to the table in their entire form, on the root.

Boston Market. Oz. 10c; lb. \$1.50.

The best variety for greenhouse culture, as the heads are small, but compact and handsome.

Bloomsdale Early Summer. Oz. 10c; lb. \$1.50.

Second early; sometimes called, by the Southern friends, "Creole."

Henderson's New York. Oz. 40c; lb. \$5.00.

One of the largest and most beautiful varieties of lettuce known. When grown to perfection on good soil, the inside of the head is white, like a cabbage, and wonderfully crisp and refreshing.

Deacon Lettuce. Oz. 40c; lb. \$5.00.

The variety is highly recommended by the Ohio Experiment Station, and so hardy that we have had good heads of it growing in the open ground as late as the middle of November. It promises to be a great acquisition.

Hanson. Oz. 10c; lb. \$1.50.

An old standard variety, producing heads that sometimes weigh as much as 2 lbs.

Brown Dutch. Oz. 10c; lb. \$1.50.

A variety that always attracts attention, and always sells on a count of the red and bronze colors of the greater part of its foliage. It is a very old variety, and the sight of it often finds a purchaser, because it reminds them so vividly of the days of childhood out on the old farm.

MELONS, MUSK.**Extra Early Citron.** Oz. 10c; lb. \$1.50.

Always profitable because of its extreme earliness.

Cassiday, or Persian Muskmelon. Oz. 5c; lb. 60c.

A standard large variety.

Pine Apple. Oz. 5c; lb. 60.

Excellent in quality, and only medium in size.

Banana. Oz. 20c; lb. \$2.00.

I consider this the best muskmelon it has ever been my fortune to taste. Judging from specimens we had last season. They are long like a rail, or like a banana, if you choose; but the color is strikingly like a banana, and, what is more wonderful still, it has an odor also like the banana. If it should prove true to the specimens we have tasted, I pronounce it a great acquisition.

MELONS, WATER.**Extra Early.** Oz. 5c; lb. 60c.

The quality is very good, but the size is not very large.

Landreth's Boss. Oz. 5c; lb. 60.

A melon that seems to combine many of the good qualities for a large late watermelon than any other.

ONION.**Extra Early Red.** Oz. 20c; lb. \$2.50.

Medium size, red, and an excellent keeper.

Silverskin, or White. Oz. 40c; lb. \$4.00.

A standard variety for pickles, or for handsome bunch onions. Better flavored than the dark-skinned.

Yellow Danvers. Oz. 20c; lb. \$2.50.

A standard yellow variety.

ONION SETS.

We have those of Yellow Danvers and Silverskin.

Prices, 10c per pint; \$1.50 per peck, or \$5.00 per bushel. Large-size sets (often used for pickles), one-half the above prices.

PARSNIP.**Bloomsdale.** Oz. 5c; lb. 40c.

This is the only kind we have, but we consider it equal to any.

PARSLEY.**Fine Curled or Double.** Oz. 5c; lb. 75c.**PEAS.****Landreth's Extra Early.** ½ pt. 5c; pk. \$1.50.

We consider this equal to any for the first peas of the season.

American Wonder. ½ pt. 5c; pk. \$1.50.

This is a cross between the Champion and the Little Gem. The vine grows from 6 to 8 inches high. It is the first to ripen among the green wrinkled sorts. On account of its dwarf habits it can be grown very easily under glass.

Stratagem. Pt. 30c; pk. \$3.00.

This has made its way rapidly in public favor. It is not only of rare excellence in quality, but the pods and peas are so large and fine looking they call attention at once from any thing else in the market. It has given us excellent satisfaction.

Yorkshire Hero. ½ pt. 5c; pk. \$1.50.

A hardy variety, considered by many to be better than the Champion.

Champion of England. ½ pt. 5c; pk. \$1.00; bushel, \$3.50.

So well known as to need no recommendation here.

PEPPERS.**Large Sweet Spanish, Bell Shape.** Oz. 25c; lb. \$3.00. Large red variety for pickles.**Bullnose.** Oz. 25c; lb. \$3.00.

A larger variety than the above, but in every other respect the same.

Cayenne Pepper. Oz. 25c; lb. \$3.00.

Much called for, for seasoning soups, pickles, etc.

Spanish Pepper. Oz. 25c; lb. \$3.00.

A new variety, so large that the natives of warm climates slice them up and fry, as an article of food.

RADISHES.**White-tipped Scarlet Turnip.** Oz. 5c; lb. 60c.

A fancy variety of the scarlet bulb with white bottom; very showy.

Scarlet Turnip-rooted. Oz. 5c; lb. 60c.

Larger and later than the preceding.

Lady Finger. Oz. 10c; lb. \$1.00.

One of the standard long radishes. Sometimes it grows as large as a parsnip, and yet is of excellent quality.

Becker's Chartier Radish. Oz. 15c; lb. \$1.50.

A novelty, and one that has given us the greatest satisfaction; of rapid growth and good size, both at the bottom and top. In favorable soil it will grow to a large size, and still be excellent in quality. The Chartier radish has been to us an acquisition during the past year. They are remarkably ear-tan to make a good bulb.

SALSIFY, OR OYSTER PLANT.

A vegetable that is sure to be called for, where it is once introduced. Oz. 5c; lb. 75c.

SPINACH.**Bloomsdale Extra Curled.** Oz. 5c; lb. 50c.

It combines as many of the good qualities as any other.

SQUASH.**SUMMER VARIETIES.****Early White Bush, or Patty Pan.** Oz. 5c; lb. 60c.

Not surpassed by the Golden Summer Crookneck. One of the old staples.

Golden Summer Crookneck. Oz. 5c; lb. 50c.

The standard summer squash.

WINTER VARIETIES.**Perfect Gem.** Oz. 5c; lb. 50c.

A round squash, about 6 inches in diameter. The quality is excellent, and it will keep till spring.

Hubbard. Oz. 10c; lb. \$1.00.

Too well known to need comment.

Boston Marrow. Oz. 5c; lb. 75c.

An old standard staple, especially in and around Boston.

TOMATO.**Mikado.** Oz. 25c; lb. \$3.50.

This tomato is so distinct from the ordinary sorts that it has a different shaped foliage that can be recognized at once. The tomatoes are of immense size, and the greater part of them smooth; besides, they are about as early as any thing we have. Some of the first last season sold at 8 cents apiece, and it does not take many such to fill a basket.

Acme. Oz. 20c; lb. \$2.00.

Too well known to need comment.

Trophy. Oz. 20c; \$2.50.

A companion to the Acme.

Livingston's Beauty. Oz. 25c; lb. \$3.50.

This is a production of the same Livingston who brought out the Acme, Trophy, Favorite, and Perfection; but he pronounces this superior to them all. The specimens at the Ohio State Fair last season were certainly all that could be desired in the tomato.

Pear-Shaped Tomatoes. Oz. 20c; \$3.00.

These are handsome for pickles and preserves. We have them of two colors—red and yellow. They are immense bearers, and of good quality.

TURNIP.**Early Bloomsdale Red Top.** Oz. 5c; lb. 60c.

One of the best for the first turnip in the market.

White Egg. Oz. 5c; lb. 50c.

Very showy and handsome, as well as quite early. Last season they sold readily for a dollar a bushel in our market as fast as we could get hold of them.

Yellow Aberdeen. Oz. 5c; lb. 50c.

We consider this the best table turnip grown. When cooked it is so yellow that it will sometimes be mistaken for squash.

Bloomsdale Swede. Oz. 5c; lb. 50c.

Perhaps the best of the Rutabaga varieties.

CUTTINGS FOR CONCORD GRAPEVINES.

In trimming our grapevines we had a great number of nice well-ripened woods which we cut up into cuttings with two or more strong buds on each. These are packed in damp sawdust, so as to keep nicely for spring planting. We can send them for 5 c. for 10, 40 c. per 100, or \$2.50 per 1000. If wanted by mail, add 16 cts. per 100 extra for postage. Full instructions for planting them will be furnished with each package. With proper care they will, in two years, furnish such grapevines as we sell for \$6.50 per 100.

A. I. ROOT, Medina, O.

HONEY COLUMN.

CITY MARKETS.

PHILADELPHIA.—*Honey.*—White clover, fancy, 15@16c; fair white-clover, 13@14c; common white-clover, 10@12. Buckwheat, 10@11. *Beeswar*, white, 26@27c; yellow, 22@24c; dark, 20@21.
Dec. 24, 1886. **PANCOAST & GRIFFITHS,**
242 South Front St., Philadelphia, Pa.

St. Louis.—*Honey.*—There is no improvement in the honey-market. Some inquiry from outside parties for round lots, but at lower prices than holders seem willing to accept. Comb honey, 10@13, as to quality and size of package. Extracted, clover, 5@6, fair to choice. Southern strained, 3@4½.
Beeswar, better demand, 21@22, as runs; 22@25 selected.
Dec. 24, 1886. **W. B. WESTCOTT & CO.,**
108 and 110 Market Street.

BOSTON.—*Honey.*—No change in prices; demand fair.
Dec. 24, 1886. **BLAKE & RIPLEY,**
57 Chatham St., Boston, Mass.

CINCINNATI.—*Honey.*—There is a quiet tone prevailing, although demand is fair for choice comb and extracted honey in small packages; manufacturers buy sparingly only. Our city has large supplies of all kinds of honey from both sides of the Rocky Mountains, and still lower prices may be expected just as soon as commission merchants are obliged to realize. The range of prices for extracted honey is 3@7c on arrival. Choice comb honey brings 12@15c in a jobbing way.
Dec. 24, 1886. **CHAS. F. MUTH & SON,**
Cincinnati, Ohio.

CHICAGO.—*Honey.*—Dull; offerings continue to increase, and, in consequence, prices are easy; sales are made in a small way at 10@12c for good comb; 12@13c for selections. Extracted, without sales to quote from. *Beeswar*, 23@25c.
Dec. 23, 1886. **R. A. BURNETT,**
161 So. Water st., Chicago, Ill.

DETROIT.—*Honey.*—The honey in sight is being gradually reduced; still there is a large supply on hand, with no change in prices. Sales of extracted very slow. *Beeswar*, 23c.
Dec. 24, 1886. **M. H. HUNT,**
Bell Branch, Mich.

PHILADELPHIA.—*Honey.*—This is a poor market, owing to the competition of glucose mixtures. White clover sells at 12@14c in glass cases. *Beeswar*, if choice, is worth 24@25c.
Dec. 22, 1886. **SAM'L S. DANIELS,**
Philadelphia, Pa.

CLEVELAND.—*Honey.*—The market is unchanged; choice 1-lb. sections of white sells slowly at 13c; 2-lbs. white, 11@12c. Second quality, 10@11. Extracted, 6c. *Beeswar*, 25.
Dec. 23, 1886. **A. C. KENDEL,**
115 Ontario St., Cleveland, O.

FOR SALE.—5 kegs (of about 180 lbs. each) of white-clover honey at 8c; also 400 lbs. basswood honey in bbl., at 7c, f. o. b. cars here. Honey is No. 1, and well ripened; packages free.
W. D. WRIGHT, Knowersville, Alb. Co., N. Y.

FOR SALE CHEAP.—4500 lbs. choice white-clover honey in 10 and 25 gal. kegs and in 48-gal. bbls.; also 2500 lbs. very fine Spanish-needle honey in 25-gal. kegs and 48-gal. bbls. Will send samples on receipt of 2-cent postage-stamp for each.
EMIL J. BAXTER, Nauvoo, Hancock Co., Ill.

FOR SALE.—I have about 1600 lbs. of nice basswood honey that I should like to sell between this and first of next month. Part of it is in molasses bbls.; 1 bbl. of 31 gallons. How much am I offered?
AMOS BLANK, Woodville, Sandusky Co., Ohio.

FOR SALE. One Barnes combined scroll and circular saw. Has fourteen circular and ten scroll saws, one cutter-head, two mandrels, three gauges, one sawset, one emery wheel, all in running order; will sell for \$35.00, which is about half cost. Address **E. C. APPLGATE,**
1-2d Poplar Flat, Lewis Co., Ky.

The "Boss" ONE-PIECE SECTIONS.

Patented June 22, 1881.

WHILE attending the North-American Bee-Keepers' Convention at Indianapolis, we learned there was a rumor afloat that the Patent on the ONE-PIECE SECTION had been set aside—circulated by unprincipled parties, to mislead bee-keepers. We would say in regard to this, that such is not the case. It is now before the U. S. Supreme Court, at Washington, and will probably be decided before a great while, when we will notify all through the Bee Journal. Until then pay no attention to rumors.

Before ordering write us for prices. We will furnish you sections as cheap as the cheapest. Let us hear from you before you order. Address

J. FORNCROOK & CO.,
Watertown, Wis.

Jan. 1, 1887.

KALER'S

Swarming - Box.

No more CUTTING LIMES! No more ABSCONDING SWARMS! No more CLUSTERING of TWO SWARMS TOGETHER! No more HARD WORK to HIVE SWARMS! EASILY done, QUICKLY done, and WELL done, with KALER'S SWARMING - BOX! Made of GOOD MATERIAL! READY for USE, at \$1.00 each.

Made to SUIT ANY SIZE OF FRAME, by

W. S. KALER,
Andersonville, Indiana.

Send postal for description. In ordering Box, give name of hive and size of frame used.

THE CHAPMAN HONEY-PLANT.

Having expended thousands of dollars in bringing before the people one of the most wonderful honey-producing plants known in the United States, or even in the world, and testing it honestly and fairly, I wish to say, through GLEANINGS, that the seed contains so much oil that nothing but fresh seed will grow for this reason; and by the advice of many prominent beekeepers I have decided to sell the limited amount of seed I have raised this season, at the following prices. I will send to those who have already ordered the amount of seed due them at this low price: ½ ounce, 50 cts.; 1 ounce, \$1.00; 2

ounces, \$1.50; 4 ounces, \$2.00; 8 ounces, \$3.00; 1 pound, \$5.00. One ounce contains from 1600 to 1800 seeds. The seed should be sown in early spring, and general directions for cultivation will be given on each package. Write all orders plainly, and give your postoffice in full.

H. CHAPMAN,
Versailles, Cattaraugus Co., N. Y.

Vol. XV.

JAN. 1, 1887.

No. 1.

TERMS: \$1.00 PER ANNUM, IN ADVANCE; 2 Copies for \$1.90; 3 for \$2.75; 5 for \$4.00; 10 or more, 75 cts. each. Single Number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canada. To all other countries of the Universal Postal Union, 18c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

SEPARATORS.

FRIEND HUTCHINSON TELLS US OF THE REASONS WHY THERE ARE SO MANY DIVERSE OPINIONS IN REGARD TO THEIR NECESSITY.

BECAUSE I am adopting Mr. Heddon's new hive, Mr. Doolittle very naturally supposes that I am also adopting separators. Such is not the case. I was so well satisfied of the advantages of Mr. Heddon's new hive that I adopted it at once, *except* the surplus-apartment. I was well satisfied with Mr. Heddon's old style of surplus case (and am yet), and I did not think it advisable to throw aside the 325 cases that I had on hand, and make those of the new style until I had decided that the latter possessed sufficient advantages to warrant the change. It was one of those instances in which there are advantages on both sides, and the question was, which had the most and greatest? While I have about 50 colonies in the new hive, I have used only 10 of the new style of super; so Mr. Doolittle will see that, instead of leaving that "better method" and "going back to separators," I am only experimenting with a style of super that allows the use of separators, and that about 95% of my crop is yet secured without separators. And right here I hope Mr. Doolittle will excuse me if I take him to task a little for his disposition to "pick up" a man if he advocates any views that he once condemned. There can be no progression without change, and it will be readily seen that new developments may lead a man to adopt views that he formerly rejected.

As to which style of case I shall eventually adopt, I can not say. If I had a quantity of either style I should not throw them away for the sake of adopt-

ing the other style. I certainly should not adopt the new style simply because it allows the use of separators; but if I used it I would then use separators; not so much for the sake of getting straight combs, but rather because, with wide frames, separators are a *convenience*.

If sections are to be glassed, separators must be used; but the indications are that this practice will not long be in vogue. If Mr. Doolittle can not abandon separators, and yet secure cratable sections, without entailing extra labor, then his hive, fixtures, or system, is such as will not profitably admit of discarding separators, and it would be folly for him to change either, simply to be able to dispense with separators. There should be weightier reasons; and if he can do no better than he reports, he is wise to retain separators.

I must take issue with him, however, in regard to the advantage gained by putting on only a small amount of surplus room at first, and very gradually increasing it. I would not be understood as advising the putting-on of an *unusually* large amount of surplus room at one time. The putting-on of a section or two at a time, or even a wide frame or two of sections at a time, involves too much labor. In the production of honey there is no factor so expensive as labor, with proper fixtures, and there never was and never will be anything gained by putting on or taking off less than a case of sections at a time. The point made by Mr. Doolittle in regard to getting off sections before they are soiled by the bees is a good one; and where the honey is finished in proximity to the brood-nest it may be necessary to remove it a section at a time, and then, of course, separators are a necessity; but with the tiering-up method, *no combs are sealed near the*

brood-nest, and the upper case can be left on until the sections are finished, with no danger of the combs becoming travel-stained.

With Mr. Doolittle's hives and fixtures, separators are undoubtedly a necessity. In fact, I fail to see how he could, as he claims to have done, given the non-separator business a fair trial; because it is only upon the tiering-up plan that separators can be abandoned with any hopes of success; and I believe that Mr. Doolittle's hives do not admit of this function.

I heartily agree with Mr. D., that we should do all we can to maintain decent prices for honey; and if any one can not secure straight combs without separators, by all means use them.

Rogersville, Mich.

W. Z. HUTCHINSON.

ANOTHER REPORT IN FAVOR OF HYBRIDS.

FROM 38 TO 91, AND 4774 LBS. OF EXTRACTED, AND 250 LBS. OF COMB HONEY.

I COMMENCED last spring with 38 good swarms and 7 light ones, making 45 in all. I had to transfer 21 of those into movable-frame hives. After this was done I built them up so when white clover came in bloom they were all in good condition, and ready for business.

I commenced extracting about the 10th of June, I believe, and closed, or stopped the extractor, just after basswood-bloom. During July and August I increased, by artificial swarming, to 91 swarms, with the exception of 7 or 8 that I got by natural swarming. I got, during the season, 4774 lbs. of extracted honey, and 250 lbs. of comb honey in one-pound sections. I sold the entire lot in my home market, with the exception of one barrel shipped to Milwaukee, besides buying $2\frac{1}{2}$ barrels of my brother, M. M. Rice, in order to supply my trade. I have received, on an average, 8 cts. per lb. for the extracted honey, and 15 cts. for the comb honey.

It will be five years next fall since I commenced keeping bees, and all I have to regret is that I did not commence 20 years before. My stock of bees is well-mixed Italians, hybrids, and blacks (and they are black too). I have been trying to find out which are the best workers for all kinds of work (laying all argument aside). I had rather have good hybrids for all work than any Italian bee I ever saw, and I have some as yellow-banded as any one else. My queens are from A. I. Root. I have a number of them. I have one very large swarm of hybrids that gave me by weight, this season, 285 lbs. of honey, besides 3 good swarms of bees. If any one should offer me \$10.00 for that hybrid queen I should be obliged to say no, for there was no end to her laying propensities. Whenever I want a lot of foundation drawn out quickly, I am sure to put it into a hive where there are hybrids or blacks.

During the last two years I have received more stings from my Italian bees than from the blacks. I will admit, that the blacks and hybrids are more irritable, and will run and leave the combs more than the Italians will, and it is harder to find their queens; for instance, when you want to clip their wings, or supersede them. But, putting up with all this trouble, I know the blacks and hybrids will make more comb honey, draw out more foundation,

do less swarming (by my own experiments) than all the Italians I have got.

B. E. RICE.

Boscobel, Grant Co., Wis., Dec., 1886.

Friend R., this question in regard to hybrids vs. pure Italians came up at the Michigan State Convention; and when I told them I had for a long time been fearing we were making a mistake in getting out every trace of black blood, it made something of a sensation; and more still when I added that we were ready to furnish hybrid queens whenever our customers asked for them. It has many times given me pain to see a bee-keeper destroy a queen that was a magnificent one in every respect, because her bees were not all three-banded. Perhaps it will be necessary for us to start another apiary to furnish a choice strain of hybrids; and I begin to think that such an arrangement will meet the wants of a great many. The price of queens reared from our best hybrid honey-gathering stocks will be the same as untested queens reared from our best imported mothers. We shall be glad to have orders early in the season, so we may know what preparations to make. I have before mentioned that we have a few customers who order hybrids every season; and if we happen to be short, and send untested Italians in their stead, they sometimes object.

MRS. COTTON.

HER CIRCULAR FOR 1887.

WE are very much pleased to note the great improvement in the above circular, and in Mrs. Cotton's mode of doing business in general. Our readers will remember that we have published several favorable reports from those using her hive and fixtures. We are very glad to do this; but in justice we can not refuse to publish the unfavorable ones as well. We have, however, consented to forward them to Mrs. Cotton before publishing them, in order that she may have an opportunity of making satisfactory any mistakes or misunderstandings.

Mrs. Cotton still recommends feeding sugar syrup to bees just before the harvest opens, and, indeed, to such an extent that they store some of this syrup in the surplus-boxes. She says this feed, when stored in the combs by the bees, can not be distinguished from the best white-clover honey by the most delicate taste. Now, while it is true that a great many might not notice a little sugar syrup mixed in with some clover honey, I think she is *greatly mistaken* in putting it so strongly as this:

The feed I use costs only about seven cents a lb., and, when stored in the combs by the bees, can not be distinguished from white-clover honey by the most delicate taste.

Again, on page 8, she says:

Under my system of management, I, by a simple process, subdue the anger of the bees, so that they can be handled without the least danger of stings.

And further along:

The members of my family are seldom stung by the bees (not one case in a year), notwithstanding I sometimes have fifty hives or more where we pass within twenty feet of them many times every day, while the bees are flying in thousands about each hive.

Now, while the above *may* be true, I believe almost every bee-keeper in our land, including those who have nothing but full-blood Italians, would say the statement is very much stronger than any thing ever ought to go into print in regard to bee-stings. On page 4 we find the following:

Swarming is controlled as completely and with as much certainty as the increase of cattle, sheep, or swine. If swarms are desired, we arrange in early spring to have them issue any week in the swarming season that will best suit our convenience, and they will swarm at the time designated.

Now, I am not positively sure that Mrs. Cotton can not do this; but if she can make her bees swarm or not swarm, as she chooses, she has gone beyond any of the veterans or experts in bee culture, at least so far as I am informed. She still charges \$4.00 for drawings and illustrations; but to modify it she offers to deduct the \$4.00 paid, from the first order for bees or hives. Her prices are still away beyond those of any other dealer in bees or supplies; but if her customers are pleased and satisfied, I do not know that we have any right to object. Perhaps the reason why her customers are satisfied, is because they are not posted in regard to the usual prices of such goods; if so, it behooves supply-dealers to let people know what other people charge for swarms of bees, both black and Italians, and other commodities.

Mrs. Cotton now furnishes her Controllable hives in the flat, to be shipped by freight. This is a very great advance over her former method of doing business. Mrs. C., in a private letter, expresses the wish to hear from every customer who is in any way dissatisfied with any dealing they have with her; and if she carries out this plan, I do not know why she should not have a place among the supply-dealers of our land.

FOUNDATION OR NO FOUNDATION.

Shall it be Used in the Brood-nest When Securing Comb Honey?

ALSO SOME FURTHER REMARKS IN FAVOR OF BLACK BEES FOR COMB HONEY.

THE last number of GLEANINGS is full of good articles as usual, and I derive much pleasure and profit from reading them. I think Mr. Hutchinson is honest in his ideas and opinions regarding the use of foundation in brood-chamber, but I am sure that rules laid down for the same in his location will not do for this locality, where we have a long slow season for surplus honey. The first honey of importance is from locust, from May 10th to 20th; then poplar about May 25th. White clover and blue thistle blossom at the same time, June 1st to 10th. These two latter sources give us most of our surplus. Blue thistle gives us a steady flow of honey to the first of September, if not too dry.

After repeated experiments the past four years, we have decided that only full sheets of fdn., put in on wire by the Given press, will do for us. Swarms hived on starters in brood-frames will not do any thing in sections until the brood-chamber is full, clear to the bottom, unless the swarm be a double one, in which case they are pushed to work

in sections for want of room. Swarms hived on starters about one inch wide usually give us from 10 to 20 pounds of honey in sections, while those hived on full frames of fdn. give us an average of 40 lbs. of comb honey. I do not doubt that, by using division-boards, and confining swarms to one-half of the brood-chamber, they would be forced to commence work in sections at once, and thereby store more surplus honey; but then we should be obliged to feed sugar to them to make up the necessary amount of stores for winter—a practice which we do not believe in. Next season we will make a more careful report on the advantages derived from the use of fdn. in brood-frames as regards amount of section honey stored.

As regards the amount of drone comb built, we think an advantage fully as great is gained by the use of full sheets of foundation; for unless we do it, some swarms will fill nearly one-third the space in brood-frames with drone comb.

We transfer a great many box hives every spring to frames; and after throwing out all drone comb and other poor comb, we do not have nearly enough to fill all the brood-frames, so we make up the deficiency with full frames of foundation, as we know by experience that transferred colonies in the spring will immediately fill the extra frames given them with one-half, at least, of drone comb, when furnished with starters only.

We are glad to see Mr. France, Heddon, and other prominent bee-keepers say a good word for the black, or native bees of this country. We, too, give them a decided preference, and would feel sick if all our comb honey were made by the Italians. We have tried queens from Alley, Thomas, Shaw, and other breeders, but have never yet seen any thing that will make any more honey, and as nice honey, as the native bees of Virginia. The native bees do not use one-half the propolis about the hive that the Italians do, and they are not so ready to follow the bee-keeper from one hive to another while operating, and pitch into what belongs to another. I have noticed, the past season, that nine-tenths of the bees entering the house and honey-house are the yellow ones, and we have only four or five stands of them out of 80 in our home apiary. The only thing I can say in favor of them is, that they defend *themselves* better against robbers, and are a little nicer for timid people to handle.

Our demand for honey has been good this season, and we have disposed of two-thirds of it at a good fair price, and we think that a good article, neatly put up, will continue to bring a fair price.

Front Royal, Va., Dec. 23, 1886.

H. W. BASS.

Friend B., I am not sufficiently well posted in this matter of Hutchinson's way of working to say just where you have failed to follow his plan of management; but at the Michigan Convention the matter was talked over so thoroughly that I became convinced that anybody will succeed as friend Hutchinson does, by observing all the conditions. These conditions have all been given at different times through the various journals; but the matter is more complex than one might imagine, and I would suggest that friend H. carefully prepare an exhaustive article, taking in all the points necessary to secure all nice honey in the surplus-arrangements. I think the whole would make a nice

little tract or pamphlet, and I should be very glad indeed to offer it for sale. Now, friend W. Z. H., roll up your sleeves and give us this little book. You can do it nicely, we all know. Let us have it before commencing another season's work.

FOUL BROOD.

STARVATION THE CAUSE.

I NOTICE on page 947, 1886, where one T. F. McCamant says, in his report under date of Oct. 18, 1886, that, "Early in the season foul brood made its appearance, and, so far as I have heard, there is no one who has not suffered more or less loss." Now, friend Root, allow me, in all justice, to enter a protest. I am living in the same section of country as friend McCamant, and have been corresponding with some leading bee-keepers living both east and west of San Antonio, and a good deal nearer to San Antonio than I do (and I am only 60 miles), and I have never heard one single intelligent bee-keeper state that he had had one case of foul brood; but I did hear one old box-hive man say that he had lost some colonies with foul brood; and when a man would come along and say his hives smelled bad, this same old bee-quack (who has been in the business 30 years, to my knowledge), would at once tell him he had foul brood, and no mistake. Now, friend R., what do you think this terrible disease was? Why, simply starvation. I examined a number of colonies which had died in this way, and I found that they had starved to death and fallen to the bottom of the hive, and, of course, smelled bad, like any other decaying mass. My friend in San Antonio evidently has not come from the field of battle, but has taken his information second hand. If friend McCamant will kindly furnish me the name and address of the leading bee-keeper who has lost so many colonies, I will sift the matter to the bottom. If it takes a trip to San Antonio to do it. I have written to friend McC. about the matter; and if the thing is a slander I will run it down, as it may injure us bee-keepers if it is not corrected. All this started last spring when bees were starving all over the country, so the story is not new to me; but I had hoped that it would not get into the papers, so I explained to all in my locality that foul brood is a disease of the brood, and not of the mature bees.

M. BROERS.

Gonzales, Tex., Dec. 13, 1886.

Friend B., you are right; but perhaps you need a little more charity. Is it not possible that friend McCamant intended to mention only his immediate neighborhood—say three or four miles from his home? In regard to the false alarm, I am sure there is a good deal of it. At the Michigan Convention one young man was telling how terribly frightened he was to find foul brood in his apiary. When we asked him how he knew it was real foul brood, he said he recognized it by the taste of the honey and by the looks of the capped combs. When some of us smiled at this test he said he would send a piece of the honey to Prof. Cook, and see if Prof. C. would not pronounce it foul brood at first sight.

SEALING JELLY-TUMBLERS WITH MELTED WAX.

HONOR TO WHOM HONOR IS DUE.

THERE, friend Root, I've found it. I knew I had seen it somewhere, and I was pretty sure it was in the *Canadian Bee Journal*. I am not apt to say a thing is so till I can prove it. Well, perhaps you want to know what I am getting at. It is this: On page 974 of GLEANINGS you speak of sealing honey-tumblers with wax, and say you "feel like giving an Indian war-whoop of exultation" when Mr. Cutting told how to do it, at the recent Michigan Convention at Ypsilanti; but he gave me the credit of the invention. I thought I had seen the suggestion either in GLEANINGS or the *C. B. J.*, but yourself and "our genial friend McPherson" denied the "soft impeachment;" and that shows that all editors don't remember every thing, any more than we "common mortals."

Now, "Render unto Cesar the things that are Cesar's," as you say, by calling attention to or quoting from the bottom of the first and top of the second columns on page 285, *C. B. J.* for 1886. We read as follows:

SEALING JELLY-TINS.

Here is a new way to seal jelly-glasses, with tin tops. Have a dish with hot wax; the wax may be kept at the proper temperature by allowing dishes containing the wax, to float in boiling water. Then take the jelly-glasses, invert them, holding them inverted, and dip them into the wax, just down to the rim, about $\frac{1}{4}$ of an inch; the wax coats the outside and top of glasses, but not the inside, for the reason that the air prevents it; besides, if it is held in the wax a short time the heat expands the air, causing the wax to settle down in the center under the glass, so a hollow may be seen in the wax under the glass; the lid is then warmed and pressed on. It not only makes it air tight at the sides, but the wax on the rim of the glass fits tight against the lid, thus sealing it nicely. Try it and see if it does not please you. These packages are becoming so popular we find them in great demand.

You speak of warming the tumblers. It seems to me it is better not to warm them, for two reasons: If warm, there will not so much wax remain on them, and they will have to be held longer to let the wax cool on them, but the covers should be made quite warm. If you could have seen Mr. Cutting and myself waxing and filling, and put the covers on a lot of glass tin-top jelly-tumblers at the Michigan State Fair at Jackson, last September, you would have seen a very interesting as well as instructive tableau. Friend Cutting was melting wax in a basin, over one of friend Hutchinson's oil-stoves, and I sat on a small box in front of a honey-extractor, filling the tumblers with honey, and W. Z. H. was leisurely walking about, enjoying the interesting scene, and, with Mr. Cutting, frequently warning as well as commanding me to be careful and not get any of the honey on the edges of the tumblers, or on my clothes. Cautious, weren't they? They hated to lose any honey, you see.

Auburndale, O., Dec. 25, 1886.

A. B. MASON.

Friend M., we own up and beg pardon. The joke comes on friend McPherson, after all. The point to it is, that it was on the first page of the *C. B. J.* for July 7, under the head of Our Own Apiary. Why didn't you keep still, old friend, and carry the credit? At any rate, we shall give you the honor of bringing the matter prominently before the public.

THE BEE-KEEPERS' UNION.

MRS. HARRISON GIVES US SOME GOOD IDEAS ON THE MATTER.

I DO not know but I'm a little off on the subject of the "Bee-keepers' Union." It appears to me a little like this: A young man from one of the remote Dutch settlements in Pennsylvania went to college, and then studied medicine. On his return to the place of his nativity, the neighbors looked up to him as a very wise and learned man, and were always sending for him to prescribe for them. In revolving the matter over in his own mind he said, "Why is it that there is so much more sickness now, than when I was a boy?" He threw up his practice and built a tanyard, and people would come to his mill and tell him of their ailments. All the answer this wise man would give was, "Do different; do different."

Since the organization of the Bee-keepers' Union, lawsuits and neighborhood quarrels are more frequent. If I should be put upon the witness-stand, and sworn to tell the "truth, the whole truth, and nothing but the truth," my testimony might be more damaging to the bees than many of my fellow-apiarists would like. It is true, that bees going to and from their hives in pursuit of honey, molest no one; but how is it when they have been roughly handled, such as is sometimes the case, when honey is being extracted?

I was at one time working with my bees, oblivious of every thing, except what I had undertaken to accomplish, and did not notice that I had angered the bees, as I was well protected against their stings. At the same time, a number of teams were employed in grading the street in front of the apiary, and I afterward learned that the drivers had great difficulty in managing them, as the bees stung them until they were almost frantic.

This fall, after the frost had killed the flowers, I was removing the surplus, and the bees were very cross. A widow owns a span of horses and a sprinkling-cart. She lives across the alley from our apiary. I almost trembled when I saw her team driven home at noon, but, fortunately, they were put in the stable without an accident. If these horses had been stung, and had run away and destroyed this woman's property, would I not have been morally responsible for her loss?

Bees are stock that we can not at all times control. If I could, I would keep them away from my neighbors' pumps. I aim to have fresh drinking-water at all times in the apiary; but it does not satisfy them. Occasionally a person or child is stung by pinching them accidentally. Some of my neighbors keep geese, and let them run at large, in direct violation of a city ordinance. These geese rest in the shade of trees upon our sidewalk, and make it foul. If I should complain to the police about these geese, how long would it be before their owners would find out that our bees were a dangerous nuisance?

Many of our Western towns have their business houses facing a public square, and the square has wells of water and hitching-posts for the accommodation of farmers and the public generally. I know a bee-keeper who has an apiary facing such a square, and is an injury to the trade of that town, for people are afraid to take their teams there, and so go somewhere else. I suppose if the authorities

should try to compel their removal he would call on the Union to defend his rights.

The Canadian bee-keepers are at present greatly agitated because one of their number is openly accused, by a neighboring blacksmith, of maintaining a nuisance, and are profuse in their offers of assistance to defend him. It appears to me that the bee-keeper is at fault, as he first complained of the blacksmith keeping a nuisance, in the shape of a bad-smelling pig-sty—a mere neighborhood quarrel, in which bee-keepers should have no interest.

Peoria, Ill.

MRS. LUCINDA HARRISON.

My good friend Mrs. H., I am very glad indeed to have you take up the defense on the other side. Your point about the geese is an excellent one. One of our neighbors keeps a large lot of chickens that have for two or three years made themselves very much at home, and apparently quite comfortable, whenever our great luscious Sharpless strawberries were in bearing. We chased the chickens home for quite a while before my wife suggested making complaint. I told her the result would be, probably, that somebody would complain about our keeping so many bees, and I thought the best way would be to fence the chickens out. This we did with poultry-netting, and the poultry-netting fence looks so pretty that I am well satisfied with the investment. It also prevents loose cattle and sheep from getting into our strawberry grounds. All these things should be taken into consideration before having differences with a neighbor; and if the Bee-keepers' Union is going to be used for the purpose of backing up one party in a neighborhood quarrel, it will certainly be a very bad thing all round. I have several times seriously questioned the propriety or right—that is, the moral right—of keeping a considerable-sized apiary very close to stores, groceries, or a public square. Perhaps if the apiary contained only a dozen or twenty colonies, and it were surrounded with close-growing trees—evergreens, for instance—so as to start the bees straight up in the air, it might not be an annoyance. Remember Paul's suggestion in regard to matters of this kind—"If meat make my brother to offend, I will eat no flesh while the world standeth."

FOUL BROOD.

FRIEND J. A. GREEN GIVES US HIS EXPERIENCE IN THE USE OF SALICYLIC ACID AND PHENOL.

THIS subject has been so much written on during the past few months in GLEANINGS that perhaps it is getting to be an old story to many of its readers. The reports of cures are so various that the person who discovers the presence of foul brood in his apiary is apt to be puzzled to know what method of cure to adopt.

The disease is so contagious in its character that promptness in its treatment is all-important, and it behooves every bee-keeper to not only acquire a thorough knowledge of its character and appearance, but to decide on the best method of cure, and be prepared to apply that cure without delay.

I have had to deal with nearly a hundred cases of foul brood of the genuine virulent type. I have

observed and worked with the disease from early spring to winter, during times of scarcity and abundance. I have tried all the remedies that seemed to me to be based on reason. I believe I am through with it now, and the hope that my experience may prove of value to others is what leads me to write this.

It seems to me that many of those who have written on the subject in our magazines have had erroneous ideas as to the nature of the disease. These ideas may be correct, as applied to their limited experience, but the method of cure adapted to one time and set of circumstances may utterly fail among other environments. I know that I have been led astray by methods that seemed plausible, and I am afraid that some of the theories lately propounded have not a very solid foundation on fact.

There are some points which need to be cleared up to the popular mind, if the disease is to be successfully combated. The usual descriptions of the appearance of the diseased brood are, for the most part, correct, but I will recapitulate.

In most cases the larva is attacked when nearly ready to seal up. It turns slightly yellow, or grayish spots appear on it. It then seems to soften, settles down in the bottom of the cell, in a shapeless mass, at first white, yellow, or grayish in color, soon changing to brown. At this stage it becomes glutinous and ropy; then, after a varying length of time, owing to the weather, it dries up into a dark coffee-colored mass. Usually the bees make no attempt to clean out infected cells, and they will sometimes fill them with honey, covering up this dried foul-brood matter at the bottom.

Sometimes the larvæ do not die until sealed over. We have been told that such may be easily detected by a sunken capping perforated by a "pinhole." This is by no means invariably the case. Such larvæ will often dry up entirely, without the cap becoming perforated or perceptibly sunken, although it usually becomes darker in color than those covering healthy larvæ.

The most fatal misapprehension has been in regard to the smell of the disease. In its first stages there is no perceptible smell, and it is not until the disease has made considerable progress that any unusual smell would be noticed by most persons. In the last stages, when sometimes half or more of the cells in a hive are filled with rotten brood, the odor becomes sufficiently pronounced, but the nose is not to be relied on to decide whether a colony has foul brood or not. Long before it can be detected by the sense of smell, the colony is in a condition to communicate the disease to others.

The eye alone can be depended on, and it must be a sharp and trained eye too, if any headway is to be made in curing the disease.

MY EXPERIENCE WITH FOUL BROOD.

When I first discovered the presence of foul brood in my apiary I knew of only two cases. I immediately introduced new queens to them, as I had had some experience with a form of diseased brood which was readily cured by the introduction of a new queen. This disease is not at all contagious, and I believe will generally if not always cure itself if let alone. I have no doubt that many of the so-called cures for foul brood have arisen from experience with this disease, or with brood which has been starved, chilled, or smothered.

Finding that this did not cure them, I resolved to

destroy them. All surplus combs and part of the hives were burned. The hives were then tightly closed, and at night a pan of burning brimstone was placed over the frames. In the morning I found that this had gone out without accomplishing its purpose. While waiting for nightfall to try it again I made a thorough examination of the apiary, and found eight or nine others with the disease. Some of these I had extracted honey from only a few days before, and there seemed no doubt that the disease would spread—as it did.

I now determined to try to cure them. Salicylic acid was most recommended then, and the Bertrand method of fumigation seemed to me the best way of applying it. All affected colonies were therefore arranged so they could be fumigated without handling combs or opening the hives. This seemed to arrest the progress of the disease somewhat; but after faithfully carrying it out for nearly two months I despaired of effecting a complete cure.

I now determined to be thorough in my treatment, so I combined the Jones, or starvation plan, with Muth's plan of feeding salicylic acid; and after starving the bees until all their honey was exhausted I put them in a clean hive on full sheets of foundation, or on empty combs, and then fed them salicylated syrup. This method was entirely successful; but winter was now at hand, and I still had several diseased colonies. After waiting until rather late in the season—all brood had been gone for some time—I extracted their honey and fed a part of them on salicylated syrup, and a part on syrup with 1-7 % of carbolic acid. All of these died during the winter except one, and that had foul brood in the spring. This spring a weak colony was robbed. An examination showed that it had foul brood, and the disease was thus scattered broadcast again.

I now tried the Cheshire plan of feeding carbolated syrup. Some were cured by it, and I now thought I had found a practical and simple cure; but before all were cured, the honey-flow began and the bees refused to take the feed.

I now returned to the starvation method without feed. I found that, when the bees were hived on foundation, they were cured; but when hived on empty combs they often developed the disease again. When hived on full sheets of foundation without starving, the disease generally returned, although a neighboring apiarist reported success by this plan with the addition of caging the queen for forty-eight hours.

A few colonies in which the disease was just starting, and only a few diseased cells were to be found, were cured by scooping out the dead larvæ, washing out the cells thoroughly with an atomizer, and spraying the surrounding comb with a two-percent solution of carbolic acid.

Several colonies, in which foul brood was unmistakably present, conquered the disease without assistance.

This was during a heavy honey-flow. I shall have something more to say in regard to the bearing this has on the case.

I now discovered that the colonies that had undergone the starvation process were far behind those similarly situated, except that they had not been starved. I then tried feeding them during their confinement, with phenolated syrup, and found it a great improvement over starvation.

By this time the fall yield of honey had come, and I still had some cases of foul brood. I shook these from their combs into a new hive with a set of sections filled with foundation above, separated by a queen-excluding honey-board from a contracted brood-chamber having only narrow starters of foundation—in short, Hutchinson's plan of hiving swarms. All these colonies not only went actively to work, filling brood-chamber and 28 sections in a very short time, but none of them showed any traces of foul brood. This was in accordance with the theory I had formed on the subject. Investigation showed that Quinby used a plan embodying the same principles, 50 years ago, and which Doolittle has more than once recommended in our journals.

Meantime a number of nuclei used in queen-rearing were attacked by the disease almost simultaneously. I overlooked them carefully, washing out all affected cells with an atomizer, then sprayed bees and combs with thin syrup containing one-seventh per cent of carbolic acid. This ended the disease.

It is not at all impossible that foul brood may reappear in my apiary, but I feel that, with the knowledge I have gained of the disease, I shall be able to speedily conquer and finally exterminate it.

With the permission of the editor I shall have something more to say on this subject in the next number of GLEANINGS, detailing what I consider the best methods of cure according to varying circumstances, with reasons therefor, and giving the exact steps so that a novice may not err.

Dayton, Ill., Dec. 10, 1886.

J. A. GREEN.

I am very, very glad, friend G., to have you indorse father Quinby's sensible views of so many years ago; and it is not very much to our credit that we have discussed the matter all this time without even thinking of looking into our old standard textbooks. I am glad to know, also, that you find carbolic acid, or phenol, at least a partial remedy. Let us have your best methods of cure.

REPORT FROM L. C. ROOT.

Something in Regard to his Honey Yields For the Past Twelve Years.

THE POSSIBILITIES BEFORE AN INTELLIGENT AND SKILLFUL APIARIST: 4103 LBS. OF LINDEN HONEY FROM 40 COLONIES IN ONLY 7 DAYS.

SEVERAL years ago, after having spent five years with father Quinby, I decided to commence bee-keeping by myself. With the benefit of our combined experience I located here, considering it the best location we could select, with all the experience we had gained in purchasing bees, honey, etc., during the years that had passed. In order to locate just where, and as I desired, I purchased the land without buildings, and arranged all with especial reference to conducting this business. The facts are, this is a very fine location, and it is a rare chance for some one who desires to take advantage of it. Under the advice of a physician, I am to remove to a salt-water location. I have purchased a place at Stamford, Ct., on Long-Island Sound. I am quite anxious to dispose of my property soon, as I have possession of my place in Connecticut Feb. 1.

L. C. ROOT.

After receiving the above from friend

Root, I wrote him that a report of his work for the past twelve years would be exceedingly interesting to the readers of GLEANINGS; and although this report may favor him in securing a customer for his place, we are glad to get it nevertheless, for it is seldom that friend Root has been induced to write on bees for any other journal than the *American Agriculturist*:

BOTH SIDES.

In answer to yours of Dec. 6, I would say that I have not reported my yields of honey of late, for two reasons. First, because many people who are in less favorable locations will not credit such reports; and, second, because reports of such yields often cause the inexperienced to engage in bee-keeping, with the anticipation of unwarranted results. Let me say, then, first, that such yields as I have secured can be gained only in very favorable locations, and with much practical experience. Beginners should not expect such results. During my first five years in keeping bees as an exclusive business, while associated with the late M. Quinby, he would frequently remark, when I made mistakes, that I was paying for *my license*. This we must all do before we shall attain success in any calling. I shall not only give some facts in regard to the best yields of honey I have taken, but also some of the reverses.

My first season, 1869, was a most disastrous one. There seemed to be absolutely no nectar in the blossoms, and nearly all stocks had to be fed for winter. The following year was a correspondingly good one, and we obtained what seemed to be an incredible yield. Some stocks gave us over 200 lbs. of box honey, and from one stock we extracted 361 lbs.

In 1874 I came from St. Johnsville to my present home. I selected this location because it offered more advantages than any other which I had seen during several years of experience in purchasing bees and honey. I commenced here with 100 colonies, in but medium condition. The first part of the season afforded me just honey enough to induce breeding, as a result of which I was able to make my stocks very populous. My first surplus was taken July 20, when linden came into bloom. During the next 40 days I secured 10,271 lbs., about one-third of which was comb honey. Since that time I have averaged good yields until the present season, which has been the poorest since 1869. Had it not been for experiences gained during that year I should not have been able to secure even the 6000 lbs. that I did from 100 stocks. If we do not become discouraged during such reverses, experiences may be gained which we can not get in any other way.

In referring to some of my best yields during the time mentioned, I do so in the belief that it may encourage some to investigate the methods by which such results may be attained. My largest average yield from an entire apiary was 9727 lbs. from 40 stocks. The largest in a given time was taken a year ago last summer, when I secured from 40 stocks 4103 lbs., all gathered in just seven days. This was gathered from linden. It is little wonder that this source of honey should fail the present season, following as it did one of such extreme abundance. This entire failure of linden honey has furnished us a great opportunity for testing some of the other sources of honey.

I have never been so thoroughly convinced of the

value of alsike clover as at present. The quality of the honey can hardly be surpassed. As you are aware, the past season also gave us great advantages for testing the merits of the "Chapman honey-plant," which seems to offer great promise for the future. Such a season also shows the wisdom of the present agitation of the subject of supplying forage for our bees, so that the sources may be greater and more certain.

L. C. ROOT.

Mohawk, N. Y., Dec. 6, 1886.

There are three points in the above, to which I wish to call attention. First, the wonderful capabilities of basswood, and that we are almost all of us destroying this beautiful tree in making honey-sections, about as fast as we can do it. How many bee-keepers are planting basswoods for the

for instance? Ere long we are going to test the matter with our 4000 young basswoods; and 4000 large trees in full bloom would probably keep 40 colonies busy, say for the greater part of two or three times seven days.

SKETCH OF THE HOME AND APIARY OF T. P. ANDREWS, FARINA, ILL.

A GLIMPSE OF THE PLACE WHERE FRIEND A. SPENDS HIS TIME.

BY way of an explanation of the engraving I will state that only about two-thirds of the hives are shown in the cut. The small building at the left is the honey-house, where the extracting is done, where the honey is kept,

APIARY AND RESIDENCE OF T. P. ANDREWS, FARINA, ILL.

rising generation? Second, I want to emphasize what friend Root says in regard to the value of honey from alsike clover. I have been able to secure about two dozen jars from the lot I have mentioned, exhibited at our Ohio State Fair. I paid about 35 cts. per jar for these, for samples. If anybody wants one before they are gone, they can have these for 40 cents. This beautiful liquid amber honey has not candied a particle at the present writing, although we have had weather below zero. Third, forty colonies may gather, in one location, over 14 lbs. a day each, on an average, for 7 days in succession. Which one of us has even a glimpse of what the future of the honey-business may be, in favorable locations—an apiary located in the midst of a basswood orchard,

and where the surplus combs, taken from the upper stories of the hives, are stored away for winter. The larger building is my workshop, and is fitted up with machinery for cutting out hive material and other fixtures.

Our honey in this vicinity is gathered mainly from coreopsis. This plant, often misnamed "Spanish needle," is very abundant in this locality, covering many of the fields after harvest with a solid mass of bright yellow blossoms. The honey gathered from this bloom has an exceptionally rich and pleasant flavor. The superior quality of this coreopsis honey is so well described by a correspondent in a recent number of the *American Bee Journal*, that I will quote his words:

"The honey produced by this plant is fast coming into public favor. Its rich, beautiful golden color,

exquisite fragrance and taste, with heavy rich body, weighing about 12 lbs. to the gallon, make it a favorite among epicures, and is sought for in our home markets above all others."

During the past 17 years bee-keeping has been my principal business, having now 300 colonies.

Farina, Ill.

T. P. ANDREWS.

We are sorry that friend A. did not take time to explain a little more. That honey-house with the wire cloth over the window fronting the audience—we want to know what is inside of it. Also that big wheelbarrow with two hives loaded on it, and with very great big whopping wheels that look like palm-leaf hats. How do you like the arrangement, friend A.? How far apart are the hives? and don't the bees get in the wrong hives more or less, when you have them so close together, and such long rows? I think you can tell us a little more about it in our next issue.

MARKETING EXTRACTED HONEY.

Something About the Right Man For Selling Honey.

EXCELLENT SUGGESTIONS FROM E. FRANCE.

RAISING large quantities of extracted honey is one thing; but when it comes to sell, and get paying prices for the honey, I confess we are not master of the situation. Still, we manage to get rid of all the honey we raise, although we have 30 barrels yet of this year's crop on hand.

Until the year 1884 our home market took all we had, except a little sold to a few neighboring towns. In 1884 we secured 31,276 lbs. of honey. The question was, whether we could sell all that honey. To make the matter still worse, three other honey-producers had sprung up, with an aggregate amount of 15,000 lbs. of honey to sell, and they were all looking to our home market to dispose of their crops. This would take a big slice off from my home trade. We were, in consequence, compelled to look up some other market. We put an advertisement in GLEANINGS, which brought an order from Messrs. Thurber, Whyland & Co., of New York. We sold them 21 barrels, and obtained cash for it, at 8½ cents. We got several other customers, some of whom are still buying of us, to sell again.

SHARKS, AND WHAT TO DO WITH THEM.

We also had an order for 12 barrels, from G. W. House, of Manlius, N. Y. We sent him the honey, and he cheated us out of our pay. But we got rid of the honey all the same. By the way, I have learned we are not the only ones whom he cheated out of their honey. Still, he has no property—poor fellow! I am very sorry for him. He is worse off than most of the parties who sold him their honey, and I should think that, by this time, he has learned that gambling and bad whisky are a bad combination. Now, the upshot of this is, when one of our number gets caught we ought to "squeal" loud enough so that every honey-producer in the country can hear it. Then the rest of us will look out and not get caught.

I bought a 1000-mile ticket on the St. Paul railroad, and took a trip out through Iowa, stopping over at almost every village. I sold honey to grocerymen, hotel-keepers, and others, to use and sell again. In that way we managed to work off the crop, besides

starting a trade with several parties who are still dealing with us.

In 1885 we had something over 30,000 lbs. of honey; but with the trade that we had worked up the year before, we worked it off without much trouble.

This year, 1886, we secured 42,489 lbs. of honey, with prices fully one cent lower than last year. But we have the honey, and have to take the market, so I purchased another 1000-mile ticket; took another trip west through Wisconsin out into Minnesota, stopping along as before, and selling in almost all the towns I visited. I went out to St. Paul and Minneapolis, and on as far as St. Cloud, Minn., then returned over another road. I was gone about four weeks. I sold a good deal of honey, but still we have 30 barrels yet to sell, and there is quite a long time yet before another crop will be harvested. I think we can work it off by that time.

SELLING HONEY, AND HOW TO DO IT; THE RIGHT MAN TO SELL.

We have sold a large quantity of honey to grocerymen and store-keepers, to sell again; but we find that the grocerymen are not the best men to sell honey—that is, extracted honey—in kegs and barrels. They won't push the sale of it. There are very few of them who will keep it in sight, or make much effort to sell. If their customers call for it they will sell. We find that, if some good honest person, one who is respected by his own town-folks, and who can take time to make a special business of selling honey, will go to every house, show the honey, either by sample or sell it as he goes, and work up a trade, supply everybody who will buy, he is the man to sell honey. Many small bee-keepers who don't raise enough to supply their own home market are good men to sell honey, as their town-folks will look to them for honey. There are a great many towns which do not, as a rule, use honey to any extent, but would use thousands of pounds every year if we could find the right kind of a man living in the town to sell the honey. I believe nearly every town or village of any importance has the right man or person to make a good salesman, and one could build up a good trade in honey, make money for themselves, and help to work off our big crops. But the trouble is to find the one to do the selling; and when they are found, they are not store-keepers, as a rule, although the store-keeper is better than no one.

I have a little story to tell, to illustrate this point: I have been in the habit for some years of going once a year around a circuit that took two or three days, and would strike five or six fine villages, to sell honey, selling mostly to store-keepers at wholesale rates, and they retail at a profit. The first year they would make some effort to sell, and would sell considerable. The next year their sales would be less, and less every year. About half way round my circuit was the town of S., of about 2500 population. The first year my man there (a store-keeper) sold 800 lbs., and sold less every year, until last year he sold only 100 lbs. Now, I made up my mind that I could do better. My wife wanted to take a ride out through the country, and so we loaded up 1000 lbs. of honey in our big spring covered wagon, and started out to go around the circuit, and do our own retailing. The first day we worked two small towns and sold 700 lbs., and drove to the town of S. We got there just at dark, too late to do any peddling, so we put up for the night at a hotel.

I had a chance to talk honey to some that night. I told them I should retail the honey myself, in the morning, at 10 cts. per lb. The merchant who had been selling, charged 15 cents, he giving me 8 cents, and was not satisfied with his profits at that. In the morning I hitched up to peddle honey over the town. My wife went along to hold the horses and see the town; but just as I was hitching on my wagon, a young man about 20 years old came to me and proposed to me to go along and help me sell honey. He said he was a carpenter's son, and that they lived in that house, pointing to a big new house on a little hill. His business had been, going to school and raising berries to sell in town. He knew everybody in town, and they all knew him. I told him, "All right, come on." So I left my wife at the hotel. The young man ran home to change his clothes a little; and while he was gone I inquired about his standing for honesty, and found him first class. All whom I asked about him said he was honest. He was soon back, and we started out. I gave him the lines and told him to choose his own customers. He drove to the doctor's house first; sold some honey; then to the houses of merchants and lawyers. Everybody knew and respected him. In a very short time our 300 lbs. of honey was gone. I saved a 5-lb. pailful of honey and gave it to him. I told him to go over the whole town and take orders with the sample, and I would send him by rail all the honey he could sell. He was to sell at 10 cents, and pay me 7, and send me my part of the money when the honey was sold. He was also to send me back the empty barrels. He agreed to that and I left him. Then the good wife and I drove home. In two days I got an order from him for a barrel of honey. I sent it (370 lbs.). In less than a week he sent the money, and ordered another barrel, one 100-lb. keg and two 50-lb. kegs. We sent the honey as ordered. In about another week he sent pay, and ordered another barrel. He said he had the town pretty well sweetened up, and was going to sell to the farmers. He soon sent cash for all he had and ordered his fourth barrel, which we sent him. Now to sum up: This young man sold over 1200 lbs. of honey in about 3 weeks. His commission was over \$36.00, and that in the same town where the merchant sold last year only 100 lbs., and growled like a dog with a sore head about there being no profit in selling honey.

We have a man in a large western town who began to buy of us in 1884. He sold the first year, four or five barrels; last year he sold 18 barrels, which he bought of us. This year he expects to sell 20 or 25 barrels of honey. He has already had 12 barrels, and we are holding as much more subject to his orders. He is a bee-keeper too. Several other regular customers are buying less quantities to sell, and the most of them are increasing their sales. We find no trouble to sell all our best grades of honey, third and fourth extracting. Of the best grades we never have enough. But our dark grades, first and second extracting, which we have always had a good trade in for manufacturing purposes, goes slow this year. There has been a flood of dark honey-dew honey this year, and it is so poor that it has played the mischief with the dark-honey trade. Some of it has been sold, I am told, as low as 3 cents a pound. We have no honey-dew honey, and I am glad of it. We have some dark honey, gathered in the spring from dandelions and fruit-blossoms, which we have been selling at 5 and 6 cents by the

barrel. We never sold our darkest honey for less than 6 cents before this year. Next year perhaps we shall be asked to give the honey, pay freight, and throw in barrels. Honey is getting lower every year—poor time for beginners to set in now.

Platteville, Wis.

E. FRANCE.

Friend F., the facts you give us in the above are very valuable, and no doubt hundreds of our readers will profit by them. The point you strike on, that so many grocers never show goods till people inquire for them, is a sad fact. Even in our own lunch-room, over and over again I find certain articles I supposed would have a good sale, put under the counters, or upon the shelves, comparatively out of sight. When I inquire about them I am told there has not been any call for them. Now, I don't suppose there would be a call for strawberries, or, at least, not very much, if the groceryman should put them under the counter as soon as they are brought in. I suppose, however, we should endeavor to make the best of humanity we can, and not grumble or find fault. Your twenty-year-old lad who learned his trade by peddling honey is the sort of chap we want. Why, it just makes me feel happy to come across one of these young fellows who love work of this kind. The fact that he knew everybody in the town was greatly in his favor. —Friend F., I want to take you to task a little for your concluding words. You have no cause to complain—that is, if you are complaining. I think you may thank God also, for giving you a queen of your household who enjoys going with you on a peddling-trip. No wonder you are a big bee-man. Don't worry about low prices. God has always provided for us, and I am sure he will to the end.

A SIMPLICITY HIVE WITH BOTTOM-BAR SHORTER THAN TOP-BAR.

THE ADVANTAGES OF A HIVE MADE TO HOLD SUCH A FRAME.

THREE years ago I invented a bee-hive which I then thought was "the hive for the South." After three years of thorough test I am now prepared to explain the hive and its merits. It is nothing more than the standard Simplicity with but a little simple change, and yet this little change makes a wonderful improvement in its manipulations and usefulness. The whole thing is easily described. The little simple change referred to consists in shortening the bottom-bar of the frame so that the hive in which the frame is to fit will be just $14\frac{1}{4}$ inches square at the bottom, inside measure, while the top of the hive and frame remains the same size as the Simplicity. The frame is shaped thus:

ITS ADVANTAGES.

Any one who has ever kept bees in the South knows something about the trouble caused by the combs melting down, even with wired frames. It was to obviate this that I constructed the new hive; and any one will see at a glance, that it is practically a great improvement, as, when the

combs start to sag, it only tightens them, the bottom of the frame being smaller than the top.

Another great advantage is, that the frames are always movable. You will notice that the least upward motion of the frame will loosen any part where the bees may have filled in with comb or propolis, and the more you lift the frame up the looser it becomes. You can really hold the frame down in the hive when you shake the bees off, thus keeping them from flying so much. It is the frame for transferring, as you will notice the comb, when cut to fit tight in the frame, will rather lie against the end-bar of the frame, and thus obviate the necessity of tying the combs in. The frame gives something like a comb of a natural shape, thus doing away, to a great extent, with the lower empty corner nearly always found in the ordinary square frame. Again, this hive gives a large space on top next to the surplus box or case—not larger than the Simplicity, but larger in proportion to the rest of the hive. I have noticed it as a fact, that the bees go more readily into the surplus-boxes. You will see from the peculiar shape of the hive that it will economize the warmth in winter. There are a great many other advantages to be had in using this hive, but experience will teach better than the pen can tell. The greatest objection is, that the hive is more difficult to make than others.

Benton, La., Dec. 17, 1886. CHARLES KINGSLEY.

Friend K., the hive you mention is not new; in fact, our friends across the water both used and described the same thing by drawings quite a number of years ago. One of the difficulties is, that you can not tier the hives up, one above another; and while we admit the advantages in lifting the frames, I believe it has been generally decided that this advantage does not overbalance the disadvantages. Heddon's reversible frame has the end-bars that go only part way down, made wedge-shaped—thus accomplishing in a measure the same thing that you do. I believe your reasons for preferring such a frame are all of them sound ones; and perhaps some of our readers may prefer to use hives made in this way; but why so great a reduction as from 17½ to 14½?

BEE-LEGISLATION.

DR. MILLER STILL DEFENDS HIS POSITION.

AS I read the remarks of Z. T. Hawk, p. 944, and the queries of A. F. Stauffer on page 947, GLEANINGS, 1886, I see plainly that there is an entire misapprehension as to the scope and bearing of bee-legislation. Bro. Stauffer asks, "Why should there be a monopoly of bee-keeping, any more than of any thing else?" I do not think there should be any more monopoly of bee-keeping than of farming. Bro. Hawk objects to class legislation. In the sense in which I think he uses it, I do not want class legislation. I want just the same legislation for bee-keepers that he wants for farmers, and that farmers have had ever since the settlement of this country.

It is possibly a little unfortunate that the word "legislation" has been used, for nowadays there is so much of jobbing and dishonesty in much of the legislation that whenever any thing is not fully understood, some hidden dishonesty is suspected. Yet, do away with all legislation, and nothing but

anarchy is left, for which we are not yet ready. For my own part I believe I desire no legislation except that which shall promote the greatest good of the greatest number. Let me briefly state the basis upon which such legislation may be asked. The successful prosecution of bee-keeping may be made a source of wealth to the country, hence is for the general good. To be successfully prosecuted, it is necessary that those who embark in the business shall be reasonably secure that any outlay of time, thought, or money, shall inure to a fair extent to their own benefit. This can hardly be, unless the bee-keeper can have a certain territory secured to his own use; and as laws now stand, he can have no assurance of this, hence the need of a new law.

The editor of GLEANINGS offers a solution of the difficulty, p. 945, which, under certain circumstances, would be very satisfactory. It is, to use the spirit that actuated father Abraham in his division of the land with Lot. But, admitting that there may be an Abraham in each case, can he be sure of a Lot to deal with? It would do away with the necessity for law in nearly all, if not all cases, if everybody wanted to do exactly right. It is just because they do not want to do right, that laws are necessary. If every one were like Abraham, or even like Lot, no one would steal; but under existing circumstances would you, brother Root, advise the abrogation of the laws against stealing? Moreover, the cases are not parallel. Abraham and Lot jointly occupied the same territory; and when the territory became overstocked an amicable division was made. To make the case parallel to the one in question, suppose that Lot, a year after the division, had brought his flocks and herds, and planted himself right by Abraham, and occupied Abraham's territory, would the old patriarch have quietly submitted to this encroachment? I trow not.

Friend Hawk says, "If the professional bee-keeper is to be protected by law against the amateur," etc. The protection I ask for is for any professional or amateur, as against any other professional or amateur who may be unwise or dishonest enough to encroach upon him, the same as the law protects the professional or amateur farmer from any encroachment upon his territory. Friend Hawk thinks no grocer should have exclusive right in any given territory. Neither do I. I think a farmer should, and friend H. thinks so most emphatically, as he says, "I certainly should resent any law that would sell to him any right whatever in regard to my farm." Why should the farmer have what he is pleased to call class legislation, and not the grocer? Because the grocer can carry on his business to his entire satisfaction with the ground covered only by his building. Limit him to a lot 30 feet square, and he may do a business of \$500 or \$500,000 per year, dependent entirely upon other things than the ground he occupies. Plant right beside him another grocer, with the same territory, and even the same capital, and one may do ten times as much business as the other, and this competition is really a necessary thing for the general good. With the farmer (as with the bee-keeper) the case is different. Take from him the exclusive control of a definite territory, and he ceases farming. His business can not be carried on without the control of that territory, and competition in his case comes in when his products are put upon

the market. Friend Hawk, don't you see that the case of the bee-keeper is like that of the farmer, and not the grocer?

Friend Stauffer, p. 947, asks if I would prevent, by law, farmers from keeping bees on their own land. I know that this will present itself as a difficulty to the minds of many. In general, the farmer has a right to do as he pleases with and on his own land; but that right must always yield to the general good, if necessary. A farmer may object to a railroad passing through his land, but if it is thought best for the general good, the railroad goes through in spite of his wishes. Between my home and the village a man erected a slaughter-house. It was on his own land, where he had a right to do as he pleased, but the slaughter-house in that location was deemed not best for the general good, and in spite of his own wishes he was obliged to take it down. I may think I can keep what plants I please on my own land; but if I attempt to raise a crop of Canada thistles I find myself mistaken. So if it be for the general good that there be encouragement to have all the nectar gathered, and to have the benefit of the bees in the fertilization of flowers, it may be the right thing to re-district the land for bee-keepers, somewhat as it was districted for farmers.

Marengo, Ill., Dec. 15, 1886.

C. C. MILLER.

BOOK AGENTS, AND AGENTS IN GENERAL.

HAS GLEANINGS BEEN TOO SEVERE ON THIS CLASS OF PEOPLE?

I THINK you are too severe on book agents. I think and know they may often do a great deal of good—are real missionaries. Many people, especially farmers, would buy but few books, except they were brought to their homes and offered for sale. Sometimes they are pressed to buy. The book is bought; and if a good one, it is a lifelong treasure to that family. I can see no reason why a book agent may not be a gentleman or a lady as well in that, calling as elsewhere, or why it is any worse to sell a book than to sell honey. Our Bible Society sends out agents.

SARAH J. W. AXTELL.

Roseville, Ills., Dec. 7, 1886.

To begin with, I am a reader of and subscriber to GLEANINGS. I should not like to be without it; but when I tell you I am, have been, and always expect to be, a "book agent," Ernest will feel like bumping a hive of hybrids to get rid of me, and you, Mr. Root, will feel like turning the "moral" in Mahala B. Chaddock's article (page 940, Dec. 1), with full force against me. But, as Mrs. Chaddock says, "there is lots of human nature in folks." I find, also, there may be lots of selfishness in folks. Now, let us examine a few articles in GLEANINGS that relate to agents.

On page 917, Nov. 15, A. I. Root throws out some very strong inducements for an agent for GLEANINGS at every postoffice. That is good so far, as I think that, if everybody read GLEANINGS we should not have to contend with so much ignorance in getting rid of our honey; besides, people would be benefited in many other ways.

But Ernest, on page 915 of same issue, takes some steps in advance of his father (which boys are likely to in these days), and tells us how to get rid of

any kind of agents. Now, suppose I should take the above number of GLEANINGS and go to one man of one postoffice, and, after trying to show him that the work was of special benefit to him, and failed, I should turn to page 915 and tell him there was an article that was worth a year's subscription. What would the man think? He would certainly be led to think an agent was something that *must* be got rid of, even if deception had to be resorted to. Now, Mr. Root, is it a *moral* fact that book agents are not needed in any community? If so, what a needless amount of time, means, and talents are expended by Bible (book) agents, and those who support them! Now, I will ask a few questions: What harm is there in taking a *good* book on any legitimate business, and trying to sell it to those who will be benefited by it? Is there any more harm in my taking the Story of the Bible to a person, and try to show him that his family will be bettered by having that book and reading it, than there is in your telling them so through GLEANINGS, as well as of the 95 other books you seem to be agent for?

I admit there are *dishonest* book agents; and what calling in life is there that does not have dishonest agents? Why are the American people so intelligent on so many subjects? Is it not because they read? How could some of our very best books be got before the people if it were not for traveling agents? Christ says the children of this world have become wiser in their generation than the children of light. The powers of darkness are flooding the world with their pernicious and soul-destroying books and papers; and shall the children of light (or children who ought to be children of light) quietly sit down and tell people how to get rid of book agents? or shall we try to present to the people the true light and work in a Christian manner with Christian spirit, with perseverance to do so?

2—T. D. WALLER, 37—83.

Port Andrew, Wis., Dec. 5, 1886.

Many thanks, dear friends, for your kind rebuke, and especially for the way in which it is given. There is, however, justice and truth on both sides of this question; but I see now that I have been altogether too sweeping, and I beg pardon. I did not mean, however, in my remarks to object to having anybody go to a neighbor's or acquaintance's. I am always glad to see a Medina man with any thing he may have to sell, provided he excuses me when I pleasantly tell him I don't want what he has for sale; and when I speak of having some one in every neighborhood act as agent for GLEANINGS I took it for granted he would go to only those with whom he is acquainted, and who would regard him as a neighbor. Most people will be quite willing to stop and listen to one with whom they are somewhat acquainted, when they would not feel pleasantly at all to be interrupted by an entire stranger, such as those who travel from house to house must necessarily be. The bee-keepers who get mail at one postoffice are almost invariably more or less acquainted with each other. The same would apply in regard to selling honey; and if I thought that any thing that has ever been said in GLEANINGS in regard to developing your home market meant that you should, by importunity and such behavior as we often meet in *book* agents, induce any-

body to buy honey they did not want, I should by all means object. There are, without doubt, two sides to this matter; but the wrong I had in mind is indeed a grievous one, and many can bear me out in saying so. I mean, overpersuading people against their better judgment. In our establishment, younger people who have not judgment and discretion have been persuaded again and again into buying books at extravagant prices when they hadn't the wherewith to pay their honest debts. A young married man was induced to buy the *Life of Grant*, when he ought not to have bought it. The same agent wanted to sell him another book, but I objected, because the young man was out in the field working *on my time*. The young man told me afterward that he was very glad I did so, for he was so much in need of money that he very much regretted having made the former purchase. Books sold by agents, so far as I know, are sold at extravagant prices, and at extravagant profits. Those who sell books, or take subscriptions for bee-journals, are satisfied with a profit of from 10 to 25 per cent; but book agents often make 100 per cent or more. In regard to religious books sold by colporteurs, I think this is indeed praiseworthy, and they ought to be encouraged; but the profits in this business are so small that a scheming and unprincipled man would never think of going into it.

The waste of time that it takes to listen to a book agent, when you don't want what he has to sell, is, to my mind, one of the greatest objections. However, you have a right to stop and listen, if you choose—that is, when you are working on your own time; but if you are working by the hour for somebody else, I do not think you have a right to stop your work and look at a book. In our establishment we have had to make very stringent rules, because of this kind of work. One lady book agent argued the matter with me quite at length. When I told her that the proper place to see our people was at their homes, outside of working hours, she replied, "But just think how much trouble it would make me to go around to all of them at their homes, compared with seeing them all together here at once." I did not tell her about the boys and the frogs, but it seemed to me that what was rare fun for her was death to—my pocket-book. If you want to sell honey, get subscriptions for *GLEANINGS*, or sell *A B C* books, don't, I beg of you, go to people who are working by the hour for somebody else, and interrupt them during their work. What Ernest put in in reference to the insurance agent was intended as a joke; but I am free to confess now, that I felt somewhat pained when I found it in print. A bee sting is, to many people, a serious matter, and we have no right to give pain to any one, especially any thing that is so excruciating as the pain of a bee-sting, either in jest or earnest. I now remember that several jokes of this kind have appeared in *GLEANINGS*, and I thank friend Waller for calling my attention to it. One who professes to follow Christ should never perpetrate jokes, nor have fun when it will give pain to a fellow-being, even if this

fellow-being has been importunate to the extent of being troublesome. There is nothing in this world that is so much to be admired as simple, frank honesty and sincerity in all our deal and in all our differences.

Friend W. strikes on another point in his remarks. I would not advise anybody to undertake to exhort a man in regard to his soul's salvation, even (without the employer's sanction), while he is employed by some one else, and while this some one else has bought and paid for his undivided time and attention. I think the cause of Christ would be furthered, many times, by remembering things of this kind. Choose a proper time and fitting opportunity, and don't say too much, remembering that the Scripture says, "Words fitly spoken are like apples of gold set in pictures of silver."

BEEES VS. BEAVERS.

A New Office for the Bee-Sting, from the *Scientific American*.

W. F. CLARKE'S NEW THEORY OF THE STING DISCUSSED.

IN order that our readers may better understand the purport of the following article from D. F. Savage, we clip from the *Scientific American*, under date of Dec. 4, page 353, the item to which our friend takes exceptions. The writer questions the scientific accuracy in such a pleasant manner that we feel that our old friend, W. F. Clarke, will not take it unkindly.

A new champion has arisen to defend the honey-bee from the obloquy under which it has always rested. Mr. Wm. F. Clarke, of Canada, claims to have discovered, from repeated observations, that the most important function of the bee's sting is not stinging. In a recent article he says:

My observations and reflections have convinced me that the most important office of the bee-sting is that which is performed in doing the artistic cell work, capping the comb, and infusing the formic acid by means of which honey receives its keeping qualities. As I said at Detroit, the sting is really a skillfully contrived little trowel, with which the bee finishes off and caps the cells when they are filled brimful of honey. This explains why honey extracted before it is capped over does not keep well. The formic acid has not been injected into it. This is done in the very act of putting the last touches on the cell work. As the little plant trowel is worked to and fro with such dexterity, the darts, of which there are two, pierce the plastic cell surface, and leave the nectar beneath its tiny drops of the fluid which makes it keep well. This is the "art preservative" of honey. A most wonderful provision of nature, truly! Herein we see that the sting and the poison-bag, with which so many of us would like to dispense, are essential to the storage of our coveted product, and that without them the beautiful comb honey of commerce would be a thing unknown.

MR. SAVAGE'S COMMENTS ON THE SAME.

Here is a strange theory of the uses of the sting of bees in slicking off the cappings of cells, and injecting therein a portion of formic acid, so that the honey may keep the better. The idea seems to be put forth in all seriousness, that the most important function of the sting is exercised within the hive, and that its occasional employment outside is only an incident or an accident. I find it in the *Scientific American*, purporting to be the substance of an article by Wm. F. Clarke, of Canada, who, it appears, made some statements on the subject at Detroit. Now, I wish to know whether any company

of bee-keepers would receive, without question, such speculations. If Bro. Clarke merely *supposes* that the bees deliberately, and in cold blood, use their stings in this way, *we* suppose that they do nothing of the sort, and one supposition is as good as another — perhaps better. He, however, claims to have come to this conclusion by repeated observations. But has he really seen the bees doing that? Does the bee, like the beaver, use the tail for a trowel? Is the latter end indeed the “business end”? There are several implements at the other end, far better adapted for smoothing and finishing off their work. I have many times witnessed, through the glass of my observing hive, the process of storing honey in cells, and capping the same with mandibles and tongue. It seems to be done in a quiet, leisurely, happy way, with no trace of anger or excitement such as invariably accompanies the darting-forth of the sting with a tiny drop of poison on the barb; for the least knock or jar is answered by a sharp yelp of resentment, and many bees are seen to spread their banners, and thrust out their weapons; but those engaged in feeding larvæ or storing honey, or comb-building, and those just coming in laden with pollen and nectar, take little notice of the disturbance, and their stings are not unsheathed. No doubt, at such a time of alarm some poison is scattered on the combs and into the honey, as Langstroth and others have remarked; and if a hive is often disturbed the honey may become very highly seasoned. We have always supposed that the unsealed honey would receive this sprinkling, not that which was sealed or nearly so. Now, Ernest, look up the authorities and see what they say concerning formic acid in honey — whether all honey contains it originally; whether it is added unconsciously while the honey is in the honey-sack, or as it is deposited in the cell, or whether it is designedly and barbarously infused at the end by the bees in order to give their plunderers the stomach-ache when they eat the stolen sweets. Does sealed honey contain much formic acid, or more than unsealed or evaporated or extracted honey? Is it the presence of the acid or the absence of air that preserves the honey? The scientists have studied these subjects, but I know not how far their conclusions will go to support the theory of Bro. Clarke; nor does it matter, unless he has really seen the thing done, as he would have us believe. In that case he has made a wonderful discovery indeed, of something wholly out of harmony with all that we have been taught and have observed concerning the habits and constitution of the bee, and the mechanism of its sting. The valiant warrior's poisoned lance has become the peaceful laborer's implement; spears are pruning-hooks, swords are plowshares, poniards are pitchforks, tomahawks are trowels. Truly, the millennium is nigh.

It would be difficult to remove the impressions that most of us have concerning the sweet satisfaction and exceeding joy of the bees in all their unmolested avocations at home and abroad; their reluctance to quarrel when honey is plentiful and they are full; their whole demeanor, so different from the irascibility displayed at other times. Friend Clarke, in his closing paragraph, discourses finely of their natural quietness, industry, and peaceableness, and in a strain that seems inconsistent with his idea that an instrument so “skillfully contrived” for offense and defense, yet general-

ly kept out of sight, but prompt to appear on slight disturbance, and that, too, with astonishing immediate effects on the community, the mere taint of the venom on the skin or clothing, or even in the air, being sufficient to awaken instant enmity and provoke a swift attack from multitudes — that such apparatus, with the feelings of displeasure, resentment, and wild fury that are inseparable from its use out of doors, should be plied so placidly and constantly within the hive.

It ill becomes a bee-keeper of prominence to add to the wild vagaries that prevailed in the former days of ignorance, and that still are held by many otherwise intelligent people. Most of the readers of such a paper as the *Scientific American*, no doubt, still suppose that bees are simply a spiteful and dangerous nuisance; and though the article referred to may enlighten and comfort them on that point, will it not create a fresh terror and panic in the minds of those who have always been hasty to believe that all bee-keepers and honey-dealers wickedly adulterate their products, and who now behold a more dangerous evil brought to light, not by an ignominious, but by a bee-master who ought to know, the fact that honey is evermore unsafe, since it is poisoned by the bees themselves at the fountain-head.

D. F. SAVAGE.

Casky, Ky., Dec. 8, 1886.

Friend Clarke says the sting is “a skillfully contrived little trowel.” My researches with the microscope, however, during past years lead me to different conclusions. All the stings I have ever examined resemble a miniature awl, made up of three smaller ones, two of which are barbed. The three are held together by grooves, “skillfully contrived” so as to pierce the skin by a sort of pumping motion. A sting may be so mounted on a glass slide in balsam as to appear a little flat. Other specimens are in danger of being perverted from their natural shape after being mounted, I find; but a sting in its normal condition, before being mounted (unless my Bausch & Lomb objective and Coddington lens are very much at fault) is simply a fine-pointed instrument like a cambric needle. As to the office of the sting curing honey or capping the cells, I have nothing to say, either pro or con.

ERNEST

HOW TO HAVE GRAPES CONVENIENT FOR BAGGING.

ALSO HOW TO GET EARLIER AND BETTER GRAPES ON THE MARKET THAN ANYBODY ELSE.

READING your article on covering bunches of grapes with paper, reminded me of what I learned about raising grapes fifteen years ago. I had in view, changing my business and trying what I could do with bees and grapes. I thought that I understood bees well enough, but was not quite so sure on grapes. So I made a trip of observation, starting at Kelley's Island, and then down the coast of Lake Erie to Buffalo. Not finding anything new I went on to Geneva, N. Y.; and on the east shore of Seneca Lake I there found the first man who knew more than I did about the business. Then I found a vineyard of Catawba grapes ripe enough to go to

market; and right over a stone fence, on the same kind of soil, the grapes were at least ten days later. What I wanted to learn was, how this was brought about. Going to the house I inquired for the proprietor, and was informed that he had gone to the lake with a load of grapes for New York city. I was invited to take a seat, or, if I preferred, go into the vineyard and look around. As this suited me best, I went out and took a look at the grapes. At that time I thought it the grandest sight I had ever seen. The vines were all healthy, and of uniform growth. Every bunch of grapes hung free and clear from any obstruction. All were good fair-sized bunches—not a small bunch in the vineyard. If he had desired to use paper bags, every bunch in the yard could have been covered.

I went back to the house and met the man, just returned from the lake, and told him I had come all the way from Michigan to learn how to raise grapes. He said he was always glad to see any one who was willing to learn. He had tried to teach his neighbors, but found they thought they knew as much (or more) than he did, so he went his own way, but year after year sold his grapes for five or six times as much as his neighbors. He had call for all he could raise, at from 25 to 30 cts. a pound, while they sold for from $3\frac{1}{2}$ to $4\frac{1}{2}$. He averaged as many pounds per acre as they did. All the additional expense he had more than they was in picking off all the small bunches soon after they had set, and freeing each bunch from all obstruction, so that it would grow in the most graceful shape.

He commenced in the spring to cultivate the soil once in ten days with a weighted cultivator, going as deep as he could, and going less deep as the season advanced, until the first of August, when cultivation ceased, except to pull up any weeds that made their appearance. The summer pruning consisted mostly in seeing that three or four vigorous canes were grown, on which to raise the next year's crop. In the fall, after frost, the vines were trimmed, and the canes left for fruiting were left to lie on the ground until spring. As soon as warm weather commenced in the spring, the vines were tied to the trellis, and cultivation commenced.

The point he most emphasized was, to raise all the fruit on large and vigorous canes, as the fruit would be larger and earlier than on weak canes; then the early and constant cultivation until about a month before ripening, and picking off all the small bunches, and straightening out all that remained, so that they would grow in the best shape for market. When placed in market the grapes sold themselves. His motto was, "Have the best that can be raised, and a few days before somebody else gets them."

L. C. WHITING.

East Saginaw, Mich.

Friend W., your communication is a most excellent one, not only for bee-keepers, but for grape-growers also. I really believe the plan you give will work almost every time, from what experience I have had with grapes. Bagging such clusters as you mention would be but a small job comparatively, and it would end the troubles among the bee-men and grape-men. The grapes around our bee-hives have improved just in proportion to the attention we have given them, and it is right in the line of your suggestions.

OUR HONEY-MARKET.

FRIEND HEDDON'S VIEWS IN REGARD TO HONEY BECOMING A STAPLE PRODUCT.

I AM glad to note friend Dadant's kind and encouraging article on page 981—none the less so because he controverts ideas of which I am convicted, especially when it is one I do not cherish. I would that friend D. were right, and I wrong; but even after reading his article I can not see it that way.

For 28 years have we been producing and introducing extracted honey, and during all this time friend D. and his class have been talking about its becoming a staple when we get it fairly introduced, and the price becomes a little lower. Well, it is now so low that those less fitted to survive at the business are "freezing out," and those best fitted to survive, calling for organized effort to stop any further slaughter in prices by all known methods, outside of the general influence of supply and demand. After all this "introducing," don't you think our people and our product ought to be somewhat acquainted with each other? Fifteen years ago I said, and to-day repeat, that it is my opinion that honey will never become a staple commodity, nor even a staple luxury, like oysters, etc. Cane-sugar syrup is a staple, or standard sweet, and at the same price would many times outsell honey, for the following reasons: First, it is two or three fold sweeter, increasing its worth for sweetening purposes precisely in the same ratio. Second, it possesses uniformity of character—a feature which enables creamery butter to command a price double that of the best roll butter, equally good. Third, I doubt if there is any honey of any color, flavor, or consistency that "wears" with the human appetite as does cane syrup. I am sorry I can not, but I do not believe that friend Muth nor any one else can work up any lasting or increasing demand for honey for purposes of cookery.

I know there are "many children who have never tasted honey," and that, too, children of those who have money enough to, and do, indulge in every luxury, notwithstanding the commodity is so very, very ancient. These children would have tasted it long ago, and many times, had it been any thing like a staple with their parents. There are too many well-to-do people who do not wish to eat it, at any price.

Yes, we have 14 grocery-stores, every one of which is well stocked with honey, 10 of which keep none except my own. This isn't all: I attend to it that they keep the jars and crates conspicuously in sight—as a rule, right on the counter. I have found, by so doing, sales are increased about three-fold. This is the strongest evidence that the article is a luxurious luxury, being as far from a "staple" as can be. It shows that, among people who are able to buy it at almost any price, they think of it rarely, except when they see it. We have cut the price in two in the middle, once, since I have been in the business, and we don't sell any more now than we did before; and if to-morrow morning we should cut it in two again, and thoroughly advertise the cut, people would say, "Did you ever?" and for a little time sales would be lively at these ruinous prices, and finally we should hear exclamations like this: "Well, I declare! after all I don't believe I like honey any better, if as well, as that nice golden syrup, and I know I don't on buckwheat cakes."

We should then find that we had caused a large number of people to conceive, for the first time, that they had many times purchased honey in preference to syrup, from no other cause than that it cost more.

I am sorry, but this is just what I believe. You told us years ago, that when honey came down to the present price there would be no end to the demand. I told you, no; nothing would stop the downward tendency of prices except lessening the production, which would come of necessity, when the weakest of us began to starve out. Well, we have reached the point, and no more honey is consumed in Dowagiac than was consumed fifteen years ago, and producers are going to hold a convention to do all that united effort can do to hold up prices, the same as is done by other classes of manufacturers.

Nearly every article of manufacture in a hardware store is sold at prices fixed by a pool. Go to your hardware store and inquire, and take a hint in time. True, honey is a product; but the method we employ to gather it and our processes in preparing it for market, rightfully class us as manufacturers, not producers.

No, no one has worked harder than I to create local demand, and Prof. McLain or any one else, acquainted with the facts, will tell you that no honey excels ours in this northern climate, and under our care of production, and we never retail any but the white, A No. 1 grades.

I agree with friend Dadant, that the *specialist* in bee-keeping will be hardly more apt to quit his calling than the farmer. But the way the small ones will drop out in the near future will, I think, be highly worthy of his notice. One peculiar fact about the farm is, that it makes a home, and supplies the greater part of a living; in fact, the whole of a possible living, whether there is any such thing as money or not, to say nothing about "prices." I have more than \$5000 invested in honey-producing, and I could not exchange it even, for any \$2000 farm in this county. I presume that the farmer whom friend Root mentions in his foot-notes had been dabbling with bees or some other side issue.

I think friend Dadant is mistaken in saying I follow his methods in producing extracted honey. So far as they are laid down in his excellent little pamphlet, many of them coincide with the methods I first adopted, sixteen years ago; but he is mistaken, and you were also, in your foot-notes to my last communication, in thinking that I continue tiering, and do not extract till the close of the surplus season. My bees gather too much honey for that, and we keep our clover, basswood, and amber grades separate.

I believe Mr. Dadant has not yet learned the value of the slatted, break-joint honey-board, shorn of which I would feel like giving up the production of both comb and extracted honey. It is against my wishes and likewise my interest in some directions, to state my convictions as above; but when drawn out upon any subject, I mean to stand by my old rule of making such statements in "the now," as I think will be verified in the future.

In closing this article I feel it an obligation and pleasure to thank friends Hutchinson and Harmon Smith for their able and instructive articles in last issue. I feel that I have profited much by both.

Dowagiac, Mich.

JAMES HEDDON.

Friend H., I agree with you to a certain extent in most of your statements, but I hope you will excuse me for saying I think you put it a little too strongly throughout almost all of your article. As an illustration, I know that many of the articles in hardware stores are sold at a regular and uniform price, while other things, and things which are staple, are sold at prices that differ very widely by different manufacturers. It is true, the *Iron Age* publishes regularly an alphabetical list of the staple hardware goods; and it also gives the prevailing discount; and this discount applies to factories north, south, east, and west. Associations are formed, but they are being constantly broken. The combination on tinware stood, I think, three or four years at one time; but in their anxiety to get orders, certain manufacturers began cutting under on the sly, and pretty soon the combination went to pieces. I still think our best way of keeping prices up on honey is to buy out the small producers before they have had a chance to run their product on to the market. It may be true, that no more honey is sold now with the present low prices than was sold before, when prices were high. But the times demand low prices on almost every thing; and what is true of honey is also true of almost all farm and rural products. Cane-sugar syrup is some sweeter than honey, if I am correctly informed, but not two or three fold sweeter. Suppose Prof. Cook straighten us out on this. And granting that it is sweeter, is it worth so much more for food? A pound of sugar may be cheaper than a pound of strawberries; but who is going to take the sugar, even if it is sweeter? Perhaps you do not call strawberries a staple; but with the tremendous trade that seems to be constantly increasing in them, I should call them a magnificent staple. Let us not waste time in arguing, when we simply have a different understanding of a certain word. The point before us is to understand how to get the most money out of the products of our industry.

AN A B C SCHOLAR'S REPORT.

A FARMER'S VIEW OF THE QUESTION—LEGISLATION FOR BEE-KEEPERS.

JUNE 28, 1884, found me in possession of a newly hived swarm of bees. They were a present to me. That swarm gathered 49 lbs. of surplus that year, and had ample stores for winter.

The spring of 1885 found them in moderately weak condition. I lifted the frames and bees out of their hive, and put them in a new clean one; and during the process I found the queen, the first I had ever seen. Being a beginner, I of course felt proud of this.

On the 9th of last June I traded a hive filled with comb, containing considerable honey, for a first swarm of bees. This swarm I call No. 2. My old swarm I call No. 1. On the 13th of June it cast a large swarm, which I call No. 3. I waited $7\frac{1}{2}$ days after this swarm issued, and then cut all queen-cells from No. 1, as per Doolittle in his review of your A B C book. It was my first experience, and proved a success. I had never even seen a queen-cell before.

No. 1 produced 155 sections. No. 2 produced 84 lbs. in boxes. No. 3 produced 135 sections.

The sections were part 1 $\frac{1}{4}$ inch and part 1 $\frac{1}{2}$ inch wide, and I use separators, so they fall considerably short of 1 lb. each in weight. But reckoning them at $\frac{3}{4}$ lb. each, they make an aggregate of 300 lbs. for the three swarms.

LEGISLATION FOR FARMERS.

I am a farmer, and have undertaken to keep bees for honey for home use; but what am I to do with it all, when the bees pile it up like this? There has been some complaint about the farmer selling honey so low that the market of the apiarist is being demoralized. Some have intimated that legislation in favor of the bee-keeper is needed. I for one would be very willing to give up my bees, could we farmers have a little legislation in our favor that would enable us to get prices, say about double what we are now getting for our farm produce. I think it quite probable that the lowest price at which any farmer ever sold honey is no lower in proportion than those at which he is obliged to sell his horses, cattle, hogs, grain, potatoes, etc. I plead guilty to having parted with 10 $\frac{1}{2}$ lbs. net honey at 12 $\frac{1}{2}$ cts. per lb., cash, and 60 sections at 11 cts. each in trade, and it was no easy matter to dispose of it, even at these figures. E. H. WHITAKER.

Peru, Ill., Nov. 27, 1886.

HOW MUCH ROOM DO THE BEES NEED FOR BROOD AND POLLEN?

IF CROWDED, IS THERE DANGER OF PUSHING THE POLLEN INTO THE SURPLUS RECEPTACLES?

MR. ROOT:—On page 94, GLEANINGS for 1885, Mr. Doolittle says: "I use six Gallup frames of comb (equal to 5 L. frames) for the very largest swarms, while others have but 4 or 5," etc. In an Oct. No. of the *American Rural Home*, of 1886, he also says: "Queens, as a rule, will not occupy more than 800 square inches of comb with brood, for any length of time," and, further along, "In order not to get any pollen in our boxes, we will allow 200 square inches of comb for that, and the little honey they always have in the upper corners of the frames, above the 800 the queen occupies." If it requires 800 to hold the brood, where will the pollen go to, when we hive our very largest swarms on 6 Gallup (or 5 L.) frames, which give but 725 square inches of comb? Is there no danger of the queen entering the sections, where side storing is practiced? or if we use dummies to contract the brood-nest, will they not swarm as soon as the queen fills the combs with brood? In hiving swarms on empty frames, according to W. Z. Hutchinson, where will the pollen go to that some of the bees of the swarm are carrying, at the time of hiving? As there are no cells below in which to place it, will it not be left in the sections, if they are supplied with full sheets of foundation or comb? I think there is pollen enough carried thus in one swarm to spoil a large number of sections, if it is put in them. How many pound sections should be given a large swarm, hived on 5 L. empty frames, or frames of comb in a good honey-flow? A little explanation of this subject would prove acceptable to me, at least.

(Ogden, N. Y.)

M. E. GRIDLEY.

AN EXPLANATION BY G. M. DOOLITTLE.

Some of the readers of GLEANINGS do not seem

to understand why it is that I should recommend a hive holding 1000 square inches of comb surface, as the right size for a brood-chamber, and then hive swarms in a hive so contracted that there is only enough room for less than 700 square inches of comb surface in it. To best explain, I will give the reader a little view of brood-rearing as I find it in this locality, after careful experiments which I have conducted for years. One queen lays all the eggs which are to become the future bees for honey or otherwise. These eggs hatch in three days, so that a small larva takes the place of the egg; this larva is fed on chyme for six days, during which it has grown from a mere speck so as to nearly fill the cell, at which time the cell is capped over. During the next twelve days this larva passes through the transformation process "from caterpillar to butterfly," and at the end of that time comes out of the cell a perfect bee, making a period of 21 days in all from the time the queen lays the egg till the bee bites off the covering to its cell. Very warm weather hastens the process of development during all the stages, and steady cool weather retards it, so that I have known the period to be shortened to about 18 days and lengthened to nearly 24, but 21 is the rule. Now, the Creator of all things designed that bees should "multiply and replenish the earth," the same as all animated things, so gave them as strong instinct to prepare for swarming as we see manifested in birds to build nests wherein to lay their eggs and rear their young. This instinct causes the queen to greatly enlarge the circle of the brood during May and June, so that, when the height of her ambition is reached (from June 10th to 20th), she lays from 2000 to 3000 eggs daily.

From experiments conducted along another line I find that, at this season of the year, some of the worker-bees, in a colony being in a normal condition, exceed 45 days as to length of life; so as the time, 21 days (from the egg to the perfect bee) is 45 days (the life of the bee at this season) we can find the reason for swarming, through the crowding of the hive. It will be seen that the queen can get 2 1-7 generations of bees on the stage of action, to where one dies off; hence comes swarming, with both bees and queen bending every energy in that direction. Swarming accomplished, the same instinct that causes the birds in midsummer to cease building nests, and prepare for a journey south in early fall, seizes hold of both bees and queen, the bees bending every energy toward getting a supply of food sufficient to carry them over winter, while the queen keeps "pace" by laying only enough eggs to keep good the population of the hive.

From this understanding of the inside workings of the hive I drew these conclusions: First, that up to time of swarming I desired a brood-chamber of the size occupied by the average queen, plus the pollen room necessary for the brood. Careful experiments gave this as 1000 square inches of comb, or 9 Gallup frames. Second, desire for swarming gratified; two-thirds of the room needed before is now amply sufficient to keep the population of the hive good, and care for the less amount of pollen now required. Besides, with the desire for less brood, pollen is gathered in far less quantities, so it is a rare thing for me to find half as much pollen in the combs surrounding the brood at this season of the year as I do in May; hence it is not often I get any pollen in sections. Again, the bees gather

no pollen, as I conclude, from basswood, which gives us our main honey-crop; for I have watched for hours at basswood-trees to find a bee with pollen on its legs. When white clover gives the main crop of surplus honey, this contraction system may give some pollen in the sections; yet I think that, if used on the above plan, not enough to do much damage. What we all should strive after, if we would be successful, is to let the bees carry out their natural instincts as much as possible, and at the same time turn those instincts to the best possible advantage for ourselves. In the above I think I have made it plain how it can be done. Herein, also, lies one of the reasons why I prefer the Italian bee to any of the others. All know that, after swarming, they show a greater desire to retrench in brood-rearing than any other race of bees, and at the same time gather unlimited quantities of honey. With the above management I throw all the early honey into the sections, while later, when the honey is of inferior color, I get enough stored in this $\frac{3}{4}$ -sized brood-chamber for winter.

One other item: Some seem to suppose that the bees seen in a swarm having pollen on their legs are bound to store this in the hive somewhere, and that, if treated *a la* Hutchinson, by using empty frames below, said pollen must go into the sections. This, I think, is a mistake; for as far as my experience goes it is "scuffed off" and thrown out at the entrance. I know it is, where the swarm is hived in an entirely empty hive, for the bees have no place to put it till comb is built, and no use for it during the first three days in any event, unless a frame of brood is inserted by the apiarist.

Borodino, N. Y.

G. M. DOOLITTLE.

OPEN OR CLOSED TOP SECTIONS.

IS THERE ANY PARTICULAR NEED OF MAKING THEM WITH CLOSED TOPS.

INASMUCH as considerable discussion and some hard feelings have resulted because we have sometimes sent open sections when our customers wanted those with closed tops, "*but forgot to say so*," we have thought best to copy the following from the A. B. J. It gives the opinion of many of our prominent honey-producers:

QUERY No. 351. "A bee-keeper in Iowa prefers closed-top sections, but in tiering up he uses open-top sections. Is it an advantage to have the first case and the one on top made thus? and will the combs (of course they can not be inverted) be as straight with closed-top sections?" Augusta, Iowa.

I see no advantage in closed-top sections anywhere.—W. Z. HUTCHINSON.

It is a disadvantage to have two sorts of sections on the same hive.—J. P. H. BROWN.

We should prefer open-top sections for every purpose.—DADANT & SON.

The combs will be just as straight with closed top as open, if you use full sheets of foundation or separators. I prefer an open-top section, as I want to "tier up."—H. D. CUTTING.

I use open-top sections, and can see no advantage in those having closed tops.—G. M. DOOLITTLE.

I should not expect combs to be quite as straight with closed-top sections, but I have never tried them.—C. C. MILLER.

I should always prefer the open-top sections. This permits tiering up, and enables one to see just what is going on.—A. J. COOK.

Closed-top sections are no advantage, as they can be made *closer* with a cloth spread over the top of the case or rack. The open-top sections are necessary to the tiering-up system, and the latter is necessary for the best results.—G. W. DEMAREE.

Never use both kinds on the same hive, or in the same apiary; in fact, never use closed-top sections at all. They are not good about getting straight combs, tiering up, handling in and out of shipping-crates, seeing the condition of the super, and so bad that they are almost totally abandoned.—JAMES HEDDON.

The combs will be built as straight with closed-top sections as with open-top ones, but the former have no advantages over the latter. I prefer a thin board with a bee-space beneath to cover the sections. Many use enameled cloth.—G. L. TINKER.

I do not think there is any advantage in using closed-top sections in any case. Open-top sections can be easily closed, but closed-top sections can not be used in "tiering up." I prefer the open-all-around sections.—J. E. POND, JR.

Several times, right in the height of the honey season, we have had customers who have declared they could not or would not use open tops. I suggested they cover the openings with wood, or some equivalent, and some of them refused to do even that. If there is another side to the question, we shall be glad to hear it; but some of the evidence must be quite conclusive.

OUR P. BENSON LETTER.

Introductory Chapter.

BEE-KEEPIN IN THE HIEST STILE.

INEVITABEL accumpennymment of troo grate-ness is modesty. That's why I am so moddest. Bein the gratest of all livin or ded apearists, mi extreme modesty prevents mi alloodin to it, hents I never say enny thing about it. But moddest as I am I feel it mi dooty to instruct the risin Jennyrat in the topick of keepin bees. If they cood all cum to me it woud be better, for I cood lern them how to keep bees in 6 short lessons without a master. It woud be much to their advantage to take lessons from the gratest sighestist in apiculturalist bee-keepin, whitch I am him. But I ken giv mutch valyouable gnawledge throo instruxion in a bee jearnal. The bee is divided in 3 parts: drones workers and kings. The drones lays the eggs. The workers makes the hunny under the direxion of the Kings whitch bosses the whole job. Layin eggs is very exostive, on whitch account the drones doant last long and generly giv out sum time in the ottem or fall of the year. When the drones dy off, the workers stop makin hunny and then eat up all the hunny by next spring. If the drones diddent dy off in ottem, the wurkers woud maik hunny all winter. I am gitting up a breed of a noo strain, whitch thair drones doant dy off so soon, and these will be moast prolifick hunny makers. Orders filled in rotashen. Satisfaxion garn-teed to enny reezenable extent, and if ennybuddy issent satisfide he ken return the munny to me.

The bee is a soshel community and never lives seppereight, 1 in a place. Some people is gilty of this, but not bees. A bee ollwaze lives in a hive and sum times in a hollough tree. A squrl also lives in a hollough tree but his tale is much more ornamental than the bee. The bee hezzent got enny tale, only just a sting. The sting is very pennytrativ in kar-riker. Moastly it gits sore whair the sting penny-trates. The bee is a verry akomodating little brute, for when it stings it ollwaze leaves its stinger in, soze to mark the place soze yule kno whair to scratch.

P. BENSON A. B. S.

(whitch the A. B. S. it stands for Apiculturalistal Beekeepin Sighestist.)

We are pleased to tell our readers that we have made an engagement with Mr. P. Benson for a series of articles on bee culture. Mr. Benson has, for many years, been resting from his arduous labors; but some of our older readers may have heard of him as a teacher of music. Since he has determined to direct his powerful intellect in the direction of bee culture, we may expect something bewildering and astonishing before he gets through.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

HONEY, BITTER, FROM CHESTNUT-BLOOM.

I HAVE read in GLEANINGS several times about bitter honey. I will tell your readers the trouble I had with bitter honey, and from where it was gathered, in the summer of 1885. I found that my bees were storing some very dark honey, and I found, on tasting it, that it had a very bitter taste; so the next day I sallied out to find out what they were working on. I followed the direction they flew, and found them working hard on chestnut-blossoms. I broke off a bunch, and found they smelled like the new honey, and tasted like that which the bees had stored in the hive. Then I knew it was chestnut honey I was getting in the sections. It is very dark. I got that year over 68 lbs. in the sections. I thought may be by age it would come all right, but it never was eatable—always a rank smell and bitter taste. I accordingly uncapped nearly all of it and placed the sections on top of the frames, and let the bees carry it below for winter stores, as they were short in the fall of 1885. They wintered all right. The cause of their storing so much chestnut honey was because the winter of 1884 killed all the white clover, and the bees had nothing but chestnut honey to gather. This year I could not see a bee working on the chestnut-bloom, so I got no bitter honey—not even a smell. I am of the opinion that this is the matter with Mr. W. H. Dickinson's honey, page 947—all chestnut honey.

JOSIAH EASTBURN.

Fallsington, Bucks Co., Pa., Dec. 9, 1886.

HONEY, BITTER, FROM CHESTNUT-BLOSSOMS.

In answer to Mr. Dickinson's inquiry in last issue about bitter honey, I will say it is probably caused by chestnut-blossoms. Chestnuts are very uneven honey-producers, and sometimes, for years in succession, give no yield; but when they do, the yield is invariably bitter—at least here in New England. Mr. Dickinson has probably these trees in his neighborhood. Remedy, keep extracted close, and save the chestnut honey to feed, or to sell to A. I. Root for medicinal purposes at an advanced price.

J. C. GREENLEAF.

Greenleaf, Mass., Dec. 6, 1886.

WORKING BY LAMP AND LANTERN LIGHT.

When Ernest works bees by moonlight or lamp-light, I wonder if he uses the smoker as by daylight, and don't the bees fly in the chimney of the lamp, and crawl over him? I tried it once, but want to know how, better, before I do it again.

MARIA L. DEMING.

Watertown, Washington Co., O., Nov. 24, 1886.

A smoker is a help when working by lan-

tern light, but I managed to get along without it; that is, I made the lantern answer somewhat the same purpose. When the hive is opened, set the lantern right on top of the frames. If any bees fly up they will strike against the globe, but receive no injury, nor will they as a rule get on to your person, as the light is a strong counter-attraction. I do not like a lamp so well—bees are too apt to get down the chimney, and burn to death. Besides, the lamp is affected by any light wind.

ERNEST.

While at the Michigan State Convention I mentioned how Ernest worked by the light of a lantern, and a good many of the friends thought it astonishing. When I got home and questioned Ernest about it, he explained as above, that the Tempest lantern was placed right on top of the frames, and kept there. Its construction is such that a bee can not possibly harm himself by it. The bees handled were all Italians, and very gentle. When the lantern was taken away it was done so quietly that none of the bees followed it. When I worked by the light of a lamp, several years ago, I placed the lamp a rod or so distant, on one of the posts forming a grapevine trellis. I have had considerable experience in trying to work with bees after it was so late in the evening that neither the bees nor myself could see, and under such circumstances I have had them get on my clothing, and buzz all over me, so that it was quite a task to hunt up the little rascals. With the light of a lamp, however, or the Tempest lantern, the matter is very simple and easy when you once "get the hang of it."

HOW DOES MR. HEDDON DRIVE BEES INTO HIS HIVING-BOX WHEN TRANSFERRING?

I have tried transferring from our box hive, but can hardly tell how much of a success it will be; but I have fully decided to have all Simplicity hives for another year. Don't you think it sets bees to robbing or fighting, to put broken combs into hives? I wish you would tell me how Mr. Heddon contrives to drive the old queen and a majority of the bees into his hiving-box from the old box hive. I can't see how it can be done without taking the old hive all to pieces (I refer to his letter, page 269, A B C book). If you can tell me, I shall be greatly obliged.

MRS. W. E. NICELY.

Mitchell Creek, Tioga Co., Pa.

My friend, it certainly does set bees to robbing, and very often to fighting, to put broken combs into the hives, unless you put them in just at nightfall, and put in only so much as they will clean up entirely, and go into their combs over night. I presume friend Heddon drives the bees out by the drumming process. If you put an empty box over any bee-hive, close all the openings, then drum on the hives with sticks occasionally, for 15 or 20 minutes, the greater part of the bees will ascend into the upper box. We have not recommended drumming in the A B C book, because we have always found it much slower than the plan I gave. See our brief references to the matter on the opposite page of the A B C book from the one you quote.

DO BUMBLE-BEES SWARM?

Will you be kind enough to tell us how the colonies of bumble-bees increase? Do they swarm as the honey-bees do, or not? And hornets also.

RECIPE FOR HARD HONEY-CAKE.

It is first rate; improves as it gets older: 6 lbs. flour; 3 lbs. honey; $1\frac{1}{2}$ lbs. sugar; $1\frac{1}{2}$ lbs. butter; $\frac{1}{2}$ doz. eggs; $\frac{1}{2}$ oz. saleratus; ginger if you like it. Roll out in cards.

E. D. HOWELL.

New Hampton, N. Y.

I think Prof. Cook will be the best man to tell us about bumble-bees. If I mistake not, he has already given us something on the subject, but we want something plain and clear, and covering the whole ground. As the matter of different races of foreign bees, including the stingless, is now prominently before us, a brief history of *their* methods of propagation would also be interesting. Can we not have it soon, friend Cook?

WHY BEES BALL QUEENS.

C. C. Miller asks, on page 938, "Is it not possible that, in this case, the bees ball their queen for the sake of protecting her?" I have thought of this very point. Such might be the case, but I no longer think it *possible*. The act of bees "balling a queen" is not one of protection, but one of aggression on the part of the bees. That they do in some instances kill the queen, even if we do at once shut up the hive and leave them alone, is another fact that goes to show it is aggression. In most cases, as the doctor says, if the hive is at once closed when we find the bees balling their queen, and they are left alone for a few days, she is *usually* released, and we find her in no way apparently damaged, except the wings are ragged from being gnawed by the bees.

—ABBOTT L. SWINSON, 71—70.

Goldsboro, Wayne Co., N. C., Dec. 13, 1886.

CARP.

I want to ask you if you are sure the small fish in the carp-pond are carp. Here a species of sunfish get in all our ponds, and many persons are deceived by the little fellows, and some have sold them for carp before learning their mistake.

OLD BEES AS NURSES.

The question is asked, "Can old bees act as nurses?" Early last spring I moved 12 colonies about 75 yards, and enough bees returned to fairly cover two Simplicity frames. They were furnished brood for queen-raising, and raised one; but she was lost, probably on her wedding-flight. Afterward they raised another, but they then had young bees from a comb of hatching brood.

DANIEL E. ROBBINS.

Pason, Ill., Nov. 25, 1886.

Friend R., our small carp may be sunfish, but I hardly think they are. Our pond has no communication with any stream containing fish of any kind.—I have been satisfied for a good while that old bees could act as nurses.

HINTS TO GARDENERS.

To destroy the striped bugs on cucumbers and other vines, fill a bucket two-thirds full of the contents of the henhouse, then fill up with water; apply the water after it has soaked a while, to the vines.

If you want to plant cabbage-plants when the ground is dry, dig a hole about 3 or 4 inches deep,

with a hoe. Pour in a pint of water, press the roots down in the mud, and pack the loose dirt on top.

If you want to keep cabbage from bursting, pull up on them till the main roots crack. This might also work with lettuce.

Should you not be heavy enough to pull, put a 25-lb. rock in your right and left coat pocket.

Pleasant Valley, Ia.

C. H. EHLERS.

Friend E., I am very much in favor of such remedies as the one you mention for striped bugs; for if it does not hurt the bugs it will make the cucumbers boom until they outstrip the bugs. Your suggestion in regard to transplanting in dry time is a good one, but it takes a good deal of time.—We have tried the plan you recommend, for keeping cabbage-heads from bursting, but it always seemed to me like locking the stable after the horse was stolen. Our cabbages sometimes burst with a pop, even while holding them in the hands. Now, then, if anybody can tell when a cabbage-head is liable to pop, he is a smarter man in that respect than I am.

FUEL FOR SMOKERS; DO BEES REQUIRE WATER WHILE IN THE CELLAR?

My wife wishes me to ask you one more question; and that is, what kind of sawdust, or what material do you use in your smoker?

Do bees require water in winter when in the cellar? Can bees be moved a mile or two safely at this season of the year?

F. F. HILL.

Barton, Vt., Oct. 26, 1886.

The sawdust used in our Clark smoker is basswood, of a rather stringy nature. It must not be too fine. For further particulars in regard to fuel for smokers, see back issues in the department of Our Own Apiary, particularly page 835.

The question in regard to water for bees while wintering in a cellar has been fully discussed in our back volumes. Prof. Cook tried giving half of his bees water, and the other half no water; and while those that had water seemed to want it, and took it up readily when offered, the result was that they did not winter as well as those that had no water at all.

SUNSHINE FOR HORSES.

That barn—yes, that barn that so many judges have pronounced the most convenient barn and stable that ever was—oh, where can the free sunlight of heaven get into those stables? They should be so arranged that the sun could shine in to purify the air and warm the stock. You built your hen-house so as to give them plenty of sunlight, and your horses and cows none (if I understand the plan as shown in GLEANINGS). It would save feed, and your stock would be in better health if confined to the barn much in winter.

G. M. HORTON.

Smithboro, N. Y., Nov. 27, 1886.

Friend H., our horses are out almost every day in the year, winter as well as summer; and while it is true that there are no windows that give them the sun, the doors are quite often left open when the weather is mild, so that the afternoon sun comes right into their faces. The largest doors of the tool-house, where the manure-spreader is kept, are seldom closed unless the weather is cold or stormy. Then there is a pretty

good-sized door in front of the passageway in front of the mangers. When this is open the sun in the winter time shines right in their faces. I think I have heard it stated, that stables should not have too much direct sunlight. Will friend Terry tell us what he knows in regard to the matter?

IN MEMORIAM OF OUR OLD FRIEND A. F. MOON.

A good many of your readers will remember the late A. F. Moon, the veteran bee-keeper who departed this life in Rome, Ga., some three years ago.

Mr. Moon, for many years, was a bee-keeper at Rome, Ga., having some two hundred hives constantly under his supervision. He made a business of raising queens mostly, and his product was sold all over the United States and Australia. From this, as well as the cultivation of flowers, which was as pleasant to him as the honey-bee, he derived a meager support; but among all his trials he was always the genial gentleman, who always welcomed visitors, and liked to "talk bees." To say that Mr. Moon was one of nature's nobleman is not to say too much. He was a gentleman in every respect, and the veteran bee-keeper of the South. At our Southern fairs he was nearly always on hand to transfer, for the amusement and instruction of the attendants, and he had learned to transfer so well and so quickly that he could complete the job in 17 minutes from the word "go."

At one of our fairs he accidentally broke his leg; and the first amputation which was necessary, being incompletely done, or done in an unskillful manner, led in after years to a second amputation from which he never recovered. He died, regretted by the entire inhabitants of Rome, among whom he had made his home for a long number of years.

Genial and warm-hearted in life, he died like "one who wraps the drapery of his couch about him and lies down to pleasant dreams." In the great hereafter, where he has gone before, may we meet again some summer day. T. E. HANBURY.

Atlanta, Ga., Dec. 9, 1886.

SELLING HONEY IN NEVADA.

I have been pretty busy putting up honey in those little glass pails, and packing my sections for market. I put 20 lbs. in a box, which I have made on purpose for them, compact and close, and each wrapped in blue paper, so when they get to their destination they are in good condition. I feel satisfied, when I hear the remarks of the parties to whom they were shipped; as, for instance, "Did you ever in your life see honey packed as nicely as this?" I tell you, I feel proud of it (but not envious) to know that all parties are satisfied. Well, now, in regard to those pails, there were two dozen broken (out of 400), but otherwise all right. If they could only make the mouth of them a little smoother it would be a great advantage to all parties. My honey is going off at good prices. For the finest of it I get 25 cts. per section in San Francisco, as well as in the adjacent counties. There is plenty of honey here that can be bought for 12 cts., but it is not so attractive, and, of course, does not sell as well as mine. I have found out that honey, as well as any thing else that is put up in proper shape, provided the quality is good, will sell, and it will pay, too, if you only take a little pains with it. That is my experience; and I know that, if we all take a little care, we can all do well.

Reno, Nevada, Nov. 26, 1886.

E. A. MOORE.

BOX-HIVE MEN IN KENTUCKY.

Of the 6074 subscribers you report in Dec. 1, No., it occurs to me that but few if any are taken on the line of my recent trip across this State and into three small towns in Kentucky. The country abounds in natural resources and box gums, but few frame hives. I saw some at only one place, and they appeared to have been neglected. Many would get movable frames if, as they say, they knew enough about bees and the management of the hives. When they found out I had no interest in patent hives and clap-traps, none to sell, but, like them, kept bees for the pleasure and profit they gave, I had eager listeners for what I had to say, and many were the questions asked, and genuine and pressing the invitations to stay all night or spend the day. They get marvelous quantities of honey in an old-fashioned, awkward sort of way. That Mississippi bottom is a great place for bees, fish, and game, and—big graveyards.

W. P. HENDERSON.

Murfreesboro, Tenn., Dec. 4, 1886.

NOTES AND QUERIES.

GREAT DROUGHT.

I SOLD my bees down to 67 colonies to commence the season with—about 50 good colonies, the rest below par. The fore part of the season was very good; the honey gathered was extra, on account of being heavy, caused by hot dry weather; but the season closed with the most severe drought experienced in this section since 1871, the fall of the great Chicago fire. I made 4000 lbs. of white-clover honey in 1-lb. sections, and about 2000 lbs. of extracted. I increased to 130 colonies, which are all in the cellar in splendid condition. I had to feed only a few pounds.

North Prairie, Wis.

W. ADDENBROOK.

How shall we make labels stick on tin?

Wheatland, Mich.

JOEL C. MERRIMAN.

[Several recipes have been given in our back volumes. Briefly, put some honey with your paste, or sandpaper the tin a little, or rub the tin with saleratus water. Lastly, use the Royal glue found on our 10-cent counter.]

OLD ROPE FOR SMOKER FUEL.

Among all the smoker fuels mentioned in GLEANINGS, I had not seen old ropes spoken of. I tie them in knots, then cut the knots apart, and they make a good and durable fuel when used with rotten wood, etc.

BURDETTE HASSETT.

Howard Center, Iowa, Dec. 10, 1886.

HOW TO KEEP POSTAGE-STAMPS FROM STICKING TO LETTERS.

If you will tell customers, when sending stamps, to rub them on their hair in its natural state it will prevent sticking together, and not injure the stamps in the least.

T. D. WALLER.

Port Andrew, Wis., Dec. 5, 1886.

[Thanks, friend W., for giving us one solution, at least, to the postage-stamp trouble. The only objection I can think of is, that if you use hair-oil you might get the stamp so greasy it would not stick when it was necessary. The other is, that "t'other fellow" might lick his tongue on his stamp after it had been rubbed on your greasy hair. But even this would be better than having them stuck fast to letters, so far as we are concerned—begging pardon if we seem selfish.]

REPORTS ENCOURAGING.

A QUEEN AND $\frac{1}{2}$ LB. OF BEES.

THE season has closed, and has been a good one all together. But little fall honey, except buckwheat. We started with 4 colonies, and increased by natural swarms to 7, besides losing two fine swarms. I bought a queen and $\frac{1}{2}$ lb. of bees of A. I. Root, received May 28. From these we have a fine colony that gave us some surplus. We have 400 lbs. of honey for our work. It is selling at only 10 cts. We hope to make even a better record next year.

Philo, Ill., Nov. 27, 1886.

M. L. BREWER.

SUM TOTAL.

My crop of surplus for 1884 was 13,500 lbs.; for 1885 was 17,500; for 1886 was 13,450.

A. B. CHENEY.

Sparta, Kent Co., Mich., Nov. 8, 1886.

SEVEN COLONIES.

This year I have got 800 lbs. of honey in one-pound boxes from seven colonies of bees.

Orangeville, O., Dec. 1, 1886.

P. MOYER.

300 LBS. PER COLONY WITH BLACK BEES.

We began this season with 7 good colonies and 3 poor ones; increased to 19, one of which absconded. We extracted about 2225 lbs. of honey, but fed back about 75 lbs.; 16 of our colonies are Germans, the other 2 are hybrids. Supposing our 3 weak colonies to have given 125 lbs. of honey (which estimate may be rather low), the other yielded 300 lbs. to the hive. If you have heard of any man in Ontario who has beaten us with Italian bees, you can let us hear of it through GLEANINGS.

J. FENNELL.

Shelburne, Ont., Can., Nov. 26, 1886.

SWINSON'S REPORT FOR 1886.

I began the season with 66 colonies, separated in four different apiaries. I ran all for queens and increase. I bred American-Albino-Italians, Syrians, and Carniolans. I sold 32 nucleus colonies, 228 queens. Received from sales of bees and queens for the season, \$275. I increased to 71 colonies, inclusive of sales. Nine-tenths of the orders were for Italian queens. During May, and up to June 20th, orders were plentiful; after that date I sold but few queens and no bees; 95 per cent of orders were for untested queens. Honey-flow was poor. All in fine order for winter.

ABBOTT L. SWINSON, 71—70.

Goldsboro, N. C., Nov. 25, 1886.

"NEVER OBLIGED TO REPORT A FAILURE:" 187 LBS. EXTRACTED HONEY, AVERAGE, PER COLONY.

I commenced the season with 175 colonies in four apiaries, from three to six miles apart. Of these, 95 colonies were run for comb honey in 1-lb. sections; the average yield was 105 lbs., and increase of bees to 145 colonies. The remaining 80 colonies were run for extracting. The average per colony from these was 187 lbs. In all, 175 colonies increased to 230; surplus honey, 25,000 lbs. Bees are all in good condition for winter; most of them have more honey than is necessary.

I have been engaged in bee-keeping for the past eleven years in different localities in this State; and although some seasons have been excessively wet and cold, and others right the reverse, yet I have never been obliged to report a failure.

Mauston, Wis., Nov. 17, 1886.

F. MCNAY.

BLACK BEES AHEAD.

I packed my bees on summer stands last winter, and left the packing around them until near swarming time, to prevent spring dwindling. The bees began to swarm in May, and got nearly through by the time my neighbor's bees commenced, which had been in the cellar. A part of my bees are Italians, which I got of friend Root; a part hybrids, the rest blacks. The blacks and hybrids led off in swarming, the blacks a little ahead, but not much; but when the Italians got at it they did not know when to stop.

Now for the honey: The Italians were a long way behind the others in the amount of honey gathered, but they are much nicer to handle. I have taken our frames of Italians several times with the queen on it, and she kept right along laying as though nothing had happened. I used Root's 1-lb. one-piece sections, and I don't want any other kind. When filled with basswood honey they are hard to beat. I secured about 2200 lbs. of comb honey.

J. B. WHITON, 46—50.

Ithaca, Gratiot Co., Mich., Sept. 28, 1886.

MYSELF AND MY NEIGHBORS.

Their feet are swift to shed blood. There is no fear of God before their eyes.—ROM. 3:15, 18.

ON the night of Dec. 22 (just after the shortest day of the year had gone) I was awakened about half-past four in the morning by the sound of fire-bells.

Now, ever since the burning of our warehouse last March, the sound of bells in the night starts me instantly until I regain consciousness enough to recognize that it is not a fire-alarm. This time, however, it was the fire-alarm for sure, but there was not any fire. The cause of it was something as follows:

About one o'clock, as the night-watchman was passing along his beat on one of our principal streets, two individuals approached him. He supposed they were boys out late at night, and accosted them pleasantly. When close to him one of them quickly swung a revolver up before his eyes while the other held a club over his head, and threatened to kill him if he moved or made a sound. He was then bound and gagged, his overcoat was tied over his head, and he was led to the court-house, where about \$40,000 was deposited in the safe of the county treasury—the taxes that had been collected preparatory to being forwarded to Columbus. There were five men all together. Three worked at the safe while the two others kept watch. They were prepared with safe-breaking tools, and plenty of dynamite; but our safe was too well made for them to get through in three hours' time. One of the sentinels announced, somewhere about four, that people were stirring, and so they were compelled to give up the job. Our marshal released himself in fifteen or twenty minutes, and gave the alarm, as before mentioned. The thieves escaped with horses and buggies taken from our citizens. The horses and buggies have been secured, but the robbers are at large.

I have often told you of talking to criminals, and men guilty of crimes of various

kinds, as I met them in our county jail. In all the cases that I remember, or nearly all, there were some extenuating circumstances. A good many of the crimes were committed while under the influence of strong drink, and sometimes I felt satisfied that the crime in question was committed when the party did not know what he was doing. Generally the criminals have repented of the act about the time I talked with them, or, at least, claimed to be penitent. I have never yet talked with a man who was on the eve of committing a crime. I have sometimes wished I could do so, in order to study more perfectly the phases of the human heart, especially of a human heart wholly given over to Satan. I have met many men who rejected the Bible; I have met some who rejected the golden rule, claiming that it is every man's business to look out for No. 1. I have talked with tramps who very honestly owned up that they did not propose to work for a living; and I have found a few who seemed so callous and hardened, that, when I asked them if they were content to have poor, weak, hard-working women cook and prepare their food while they did nothing, would, when pressed hard, say they did not care. Such individuals, however, seem hardly human, and I have sometimes been tempted to think they were about half way between the brute creation and humanity, and right in the midst of civilization too. It seems to me that Darwin might have accepted these phases as his "connecting link." These five men of whom I have been speaking, however, without question deliberately and with premeditation not only rejected God and the Bible, but they rejected Christ and his teachings; they rejected the golden rule, and they declared by their actions that they did not care whose money it was, nor what it cost to get it. They were willing to sacrifice every thing—the chances of being shot themselves, and the probability of committing murder themselves, for a few paltry dollars. These dollars were the hard, scraped-up earnings of the farmers of Medina County. These five men were probably aware of the fact that farmers have had a terribly hard row to hoe in raising wheat at 75 or 80 cents a bushel, corn for 20 or 25, and other things in proportion. They recognized how hard it has been for many of the farmers to scrape up enough money to pay their taxes; and yet they would, without scruple, appropriate the hoarded earnings of our county. In the language of our text, "There is no fear of God before their eyes." They had sold themselves to the evil one; and when I want to be reminded that Satan is actually at present finding a lodging-place in the hearts of men in this nineteenth century, I have only to think of the state of these men's hearts. Some of us are beginning to think that stories of highwaymen are getting to be a thing of the past. Alas, my friends, they are *not* a thing of the past. In spite of our schools and churches, and the progress we as a nation are making in civilization and Christianity, our papers contain accounts like these continually. Woe betide us if we sit down and fold our hands, thinking the victory is won. If we banish

saloons from our land, it may have the effect of somewhat lessening this sort of work; but I am afraid that not all of these men can plead the poor excuse of being hard drinkers. I have been told there are men of this class to be found who are never intoxicated at all. Suppose it were possible to sit down and have a talk with such as they while the purpose was in their hearts of committing these crimes, what sort of defense would they make? Every rational human being is, as a rule, prepared to defend his course. A great many commit crimes through revenge; and I have heard men admit that they would risk death itself for the sake of indulging their passion to pay back somebody who had wronged them. Men sometimes commit murder because of dwelling on fancied or real injuries, and let Satan into their heart in this way. These robbers, however, of whom I speak, had no revenge in their hearts; they had no ill will toward the marshal, whom they threatened to kill. When they started away, one of them took the overcoat from off the marshal's head and folded it up for a pillow for him to lie on, indicating that there was a *spark* of humanity of one kind in their hearts yet. They had no disposition to do him harm, only so far as it was necessary to get the money. In view of this, what, then, is the remedy? Simply Christ Jesus. This class of men are as far away from the Bible and Bible teachings as it is possible for any thing to be. The Bible is at one side, and they are far away off on the other side. A great gulf lies between them and Christ's spirit and his teachings. They were prepared to commit deliberate murder—yes, even to murder those who had never wronged them nor injured them. We call a man heroic when he gives his life for his *friends*. Christ gave his life to save his *enemies*. Does it not seem almost hopeless to try to put the difference on paper, between Christ's spirit, or even that of a Christian man in whom Christ's spirit has found a lodging-place, and these men in whose hearts Satan has found a lodging-place? I wonder if they know any thing of the teachings of the Bible; I wonder if they have ever at any time in their lives thought of becoming Christians. My mind follows them, dear readers, because they are my neighbors. It is true, they do not live in Medina—at least, I hope they do not; but the spirit that actuates them is finding a lodging-place, to a greater or lesser extent, in the hearts of humanity all round about us. These events have this effect upon myself: They make me love the Bible more than I ever loved it before, and they make me love good, honest, God-fearing men more than I ever loved them before; and I turn with renewed joy and thankfulness to that promise in the sermon on the mount—"Blessed are the meek, for they shall inherit the earth." Through Christ this evil spirit is to be conquered and driven out; and upon Christian people rests the burden and responsibility. It rests with such as we are, sinful and imperfect, to hasten the time when God's kingdom shall come and Christ's will be done in earth as it is in heaven.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

SUITABLE DRESS FOR WORKING AMONG THE BEES.

Conveniences for the Apiary—Continued.

TO work among the bees to the best advantage during hot weather, I deem it highly essential that the apiarist pay due attention to the matter of dress. He should be so attired that he can work with comfort as well as convenience, burning hot though the sun may be. His clothing should be rather cheap, and not easily injured by honey dripping.

Constitutions are so widely different that what will be applicable to one will not be to another. Some will be easily affected by the sun's heat, others from profuse sweating. In the face of these circumstances I am not sure that I can recommend a dress suitable for all. But I fancy that many of my readers are constituted like myself.

I once thought I was not adapted to summer work out in the apiary. The sun's heat completely "played me out," as I was wont to express it. But I wore no underwear. In fact, I was attired in about the same dress that Dr. Miller says he wears;* namely, "One straw hat and veil, one cotton shirt, one pair of cotton overalls, one pair of cotton socks, and one pair of shoes." He further states, that about noon he sponges himself off and puts on dry clothing in place of that which is wet with sweat. The latter is put out to dry, to be used the next day.

Unlike Dr. Miller, I never could sweat enough to keep sufficiently moist to counteract the burning rays of the sun. The single thickness of cotton cloth of one shirt was not enough to prevent my back from blistering. The heat on such occasions, when I was attired thus, seemed unbearable, and I had a burning desire to get to some cool shady nook. Not only this, but the sun's rays made me feel dizzy at times, and a sort of sickness, which I thought savored of sunstroke, came over me.

The next summer, in addition to the cotton shirt, I wore an undershirt—the latter not heavy, part cotton and part woolen. I was aware of the fact that many wear their underwear the year round, claiming that it protects them, not only from cold, but from extremes of heat. I likewise noticed, in works on health and hygiene, that underwear is recommended. Influenced by this, I decided that, at the approach of warm weather, I would not cast aside my underwear as usual. The following summer in the apiary attested the wisdom of this decision, and I nevermore experienced any inconvenience when working in the hottest sun. The woolen not only proved a great protection, but stopped the speedy evaporation of perspiration—what little I do have. The moist woolen, for me, has a delightful coolness which is indeed refreshing. I have gone directly from the hot sun in the apiary to the office. The latter place seemed oppressively hot, while in the open air I felt very com-

fortable. Mind you, it was right the reverse when I formerly worked among the bees with but one thickness of cotton cloth over my back.

My experience may be a little singular; but, fellow-apiarists, if you are troubled much by the heat of the sun, try light underwear the coming summer. I feel sure that some of you will find it a decided advantage, while others may be so constituted as to prefer the dress recommended by Dr. Miller. I don't know, but it seems to me a light underwear for our friend the doctor might prevent such profuse sweating; but it may be that experience has taught him to the contrary.

A SUITABLE HAT FOR THE APIARY.

Reasoning from the foregoing, my readers might naturally suppose that I would recommend a heavy hat. Not so. I prefer a light hat—the lighter in weight the better. That you may get a better idea of the one I prefer, I will ask the reader to turn back to the cut on page 1001, last issue. The accompanying engraving shows the same hat, but not so closely. The covering is cloth, and of a light drab color. The brim is held out in position by a light steel hoop. The crown on the inside is so made that it will fit any head. This is accomplished by means of a light rubber band sewn into the cloth crown. The lower side of the brim is covered with green cloth. When it is on the head, one is scarcely aware that he has any head-covering, so very light and easy is it. The broad brim, with the green on the under side, has a softening effect on the eyes, and completely shades them from the glare of the summer sun. When the latter is very hot I pull a couple of large plantain-leaves, or, better still, a large grapevine-leaf, and place it in the top of the hat.

"Why isn't a broad-brim palm-leaf or straw hat as good?" you ask. In the first place, they are much heavier, and warp into shapes that are outlandish, to say the least, after a little use. The average farmer will go about with a thing on his head that looks more savage than civilized. Again, in a hot burning sun I can not bear to have a hat pinch tightly around my head—it gives me the headache. The cloth one I have just described is entirely free from this latter objection, and, on the contrary, is so constructed as to give a comparatively free circulation of air about the forehead. I have used this style of hat four or five summers, and therefore take pleasure in recommending it. In a future number I will tell how well this hat is adapted for holding a veil.

Before leaving this subject of hats, I wish to say that I think, upon inquiry, they can be purchased in their season at most of the clothing-stores. They retail at 25 cts. each. In the meantime we will see what we can do in the way of furnishing them for next season's use, should there be a call for them.

STRAW CUFFS TO PROTECT THE WRISTS FROM STINGS, AND TO PREVENT SOILING THE SHIRT-SLEEVES.

My readers will please take a look at the cut on p. 1001, last issue, as well as the one opposite, for a view of the cuffs. You ob-

* A Year Among the Bees, p. 64.

serve that they are made of straw, closely knit, and large enough to cover the sleeve half way to the elbow.

When working among the bees I always like to have my shirt-sleeves draw up a little from the wrist. They are held up by coiled wire garters. This draws the sleeve tightly about the wrist, and prevents, to a great extent, bees crawling up. But whether the sleeves are drawn up or not, the bees are liable to sting the exposed parts of the wrist, which, when stung, with me, the pain is exceedingly sharp. To protect myself during past seasons I wore the straw cuffs. You notice they drop down close to the hands, so that, when a bee crawls up the latter, being unable to walk under, he crawls up the cuff.

In autumn weather, during fall feeding, for instance, when it is comfortable to wear

ducking, the ordinary material. Those made of linen are in general a better fit. The ordinary overalls are so ill fitting and baggy that I am afraid I should be ashamed to be introduced to visitors when attired thus, especially if father should come out (as he is liable to do) and say, "Mr. Jones, this is my son. He will take great pleasure in showing you about."

In warm weather I prefer low shoes and light cotton socks. If the grass is wet with dew in the morning, as is often the case, I slip on rubbers. Lately, however, I have found something that I like a little better than rubbers; i. e., light rubber boots designed for ladies. I think I shall prefer the latter, for the reason that they keep the bottom of my pants dry, which rubbers sometimes fail to do.

THE APIARIST AT WORK OVER A HIVE; ALSO SHOWING HIS MANNER OF DRESS.

a coat, the sleeves of the latter may be tucked into the cuffs, and thus prevent the bees crawling up the mouth of the sleeve, which always seems especially inviting to a bee, especially if hybrid or black. As stated in the heading, the cuffs are useful in another respect; namely, keeping the coat or shirt sleeves clean from honey or wax. Our boys have, therefore, found them invaluable when transferring, or in any other job where one is liable to get his fingers sticky.

OVERALLS.

If I intend to work for any length of time among the bees, I invariably don a pair of overalls as you see. The kind I use are made of a fine quality of blue linen — not

Having now for the present disposed of this matter of dress, perhaps you inquire what the fellow in the picture is doing. I intended, among other things, to illustrate how I use the Simplicity-hive cover for a stool. I sit down to a hive thus, when I become tired of stooping when on my feet, and, as you see, the cover answers admirably. Indeed, I think it is a far better substitute than a tool-box, which has to be lugged about. The stool is always ready as you see.

I had intended to mention one or two other items in this connection, but as the "boss printer" says my room is limited, I will defer them until next issue.

REPORT OF THE COMMITTEE ON THE CHAPMAN HONEY-PLANT.

WRITTEN OUT BY PROF. McLAIN.

AS considerable space has already been given to reports in regard to this plant, we thought it hardly worth while to go over the ground again; but as friend Chapman particularly wishes a full report from all the members comprising said committee, we subjoin the following:

The committee appointed by the North-American Bee-Keepers' Society, at the annual meeting held in Detroit, Mich., December, 1885, to investigate the merits of a honey-bearing plant now being cultivated by Mr. Hiram Chapman, of Versailles, N. Y., met at that place July 25, 1886. One member of the committee, Mr. Manum, of Bristol, Vt., was not able to be present; but as each member of your committee was furnished with a sufficient number of plants to afford opportunity for observing their growth and habits, and also to gain some information concerning the value of the plant as a honey-producer, a letter from Mr. Manum, in which he gives the result of his experience and observation, is herewith appended. This plant, which Dr. Beal, of the Michigan State Agricultural College, and Mr. Scribner, Asst. Botanist of the U. S. Department of Agriculture, tell us is *Echinops Sphaerocephalus*, is an imported perennial, native in Central France, and, like all of the family to which it belongs, very rich in honey.

This plant will probably be popularly known in this country as the "Chapman honey-plant," so named on account of Mr. Chapman being first to cultivate it, and being first to bring it to the notice of bee-keepers. We found three acres of the plant in bloom. The height of the mature plant is from 3 to 4½ feet, and each root bears from 5 to 15 round balls, or heads, from one inch to 1½ inches in diameter. These heads stand upright, and the entire surface is covered with small white flowers having bluish stamens.

The stalks and leaves so nearly resemble those of the common thistle, that, were it not for the head, the difference would not be easily noticed. There is, however, in this particular, a very marked difference, the appearance of the head being aptly described by its botanical name, which signifies round-headed, and in appearance like a hedgehog. The flowerets on top of the head open first, then they open later along the sides of the ball, continuing in the order of nature around the entire surface of the sphere. Near to the stem the last flowerets open after the blossoms on the tops of the heads have disappeared, and the seed-capsules of the first blossoms have hardened.

Unlike the thistle, the seeds are provided with no balloon by which they may be borne by the wind. The seed is, in weight and appearance, very much like a small grain of rye; is inclosed in a capsule, and falls directly to the ground, if not seasonably gathered, not spreading more than oats, if left to fall without harvesting.

From the time of the appearance of the bloom upon the tops of individual heads until the fading of the last blossoms upon the lower part of the head near to the stalk, is about eight days; the continuance of the blooming depending upon the nature of the soil and the season; but the heads, or buds sent out from each individual shoot, and forming each individual cluster, vary in degree and size, so that the natural term of blooming and honey-bearing may safely be reckoned at from 20 to 30 days. The term of blooming may also be prolonged to a considerable extent by cutting back a portion of the plants, and the facility with which the honey-harvest may thus be prolonged constitutes an important feature when estimating the value of this plant. The plant is hardy, easily propagated, perennial, and appears to flourish in all kinds of soil, and there is no danger of its becoming a pest or a noxious weed. It does not bloom until the second season; and as it does not spread in seeding, its extirpation would be easily accomplished. Its seed may be scattered in waste places, or it may be sown in drills or hills, like onion seed. It seems to be characteristic of the plant to root out all other vegetation, and take possession of the soil. No weeds, and but very little grass, was seen growing in the three-

acre plot observed. A ten-acre field, sown broadcast and harrowed in like rye, has also made a vigorous growth, and seems to be taking possession of the soil, in opposition to quack-grass and weeds. As to the value of the plant to the honey-producer, there appears to be no room for doubt, whether quantity or quality, or both, be considered.

Within reach of Mr. Chapman's apiary, no other resources were accessible for honey-gathering. The severe and prolonged drought destroyed all other honey-yielding blossoms, and yet in some instances the bees were making an excellent showing in the hives. No definite conclusion could be reached as to the probable returns in pounds of honey from a given area. That the returns would be satisfactory, was evidenced by the fact that the entire area was "alive with bees," and they visited the flowers from daylight until dark, and sometimes eight or ten bees were upon a single head at one time. Mr. Hubbard, who cultivated some of these plants obtained from Mr. Chapman, represented that he had counted the number of visits made by bees to a single head from 5 A.M. to 7 P.M. He reported the number as being 2135, actual count. In order that the committee might have some idea of the quantity of nectar secreted in the flowers of a single head, the day before our arrival Mr. Chapman had wrapped a thin paper about a head, the half of which was in full bloom, and tied the paper around the stem with tape, thus preventing the bees from appropriating the nectar for 24 hours. Upon removing the paper on the forenoon of the day of our visit, the flowerets were found to be dripping with nectar, and the drops sparkled in the morning sun. Each of us have made similar tests with like results since that time. We cheerfully and confidently recommend this plant to the bee-keepers of North America as a most valuable acquisition to the list of bee-forestage plants.

We believe that a trial of the plant will, better than any further words of approval from us, publish its own commendation.

Respectfully submitted,

N. W. McLAIN.

A. I. ROOT.

L. C. ROOT.

The following is a report in regard to the plant, from Mr. Manum, who was absent at the time the other members of the committee assembled at Mr. Chapman's:

L. C. Root, Chairman of Committee on the Chapman Honey-Plant.—Dear Sir:—As I failed to put in an appearance when the committee met at Mr. Chapman's, in July last, it is not only due you, but to Mr. Chapman and the convention as well, that I make a short report of my experience with the Chapman honey-plant, 50 roots of which Mr. Chapman so kindly sent me last spring. The plants thrived well through the summer, under moderate cultivation, and planted on light sandy soil. I did not take extra pains with them, as I wished to test their hardiness. The plants commenced to bloom July 14, and continued to bloom until Aug. 21, making 39 days that they continued in bloom; and from the first day of their blooming until the last, the little flower-balls were covered with bees every day from early morning until dark, rain or shine (we had no very heavy rains during this period), the bees constantly going and coming. I have counted 16 bees on one ball at one time, all sucking the sweet nectar from the richly laden flowers of the Chapman honey-plant. At Mr. Chapman's request I covered 3 of the balls with tissue paper, and 2 with muslin. On the following day there were several bee-keepers here. I removed the paper from the balls, and, lo and behold! the flowers were filled—yes, covered, as it were, with honey. We found, by holding the hand under one of the balls, and jarring it, the honey dropped in the hand enough to make several drops. In a moment a bee alighted on one of the uncovered balls, and never moved until its sack was filled, when it flew away. On timing them I found that five bees filled themselves and flew away in two minutes and twenty seconds from the time the first bee alighted on the plant. The two balls that were covered with muslin were now uncovered; but the honey seemed to have evaporated, as there was but little visible, although I had noticed bees alight on the muslin, and try to suck honey through the cloth. This fact was conclusive to me that the bees could smell the honey through the cloth. I find that, by cutting

back the plants in June, they will bloom later in the season. This would be of advantage, perhaps, to those who are favored with an abundance of buckwheat for their bees to work on during August, as, by cutting it back, it would then commence to bloom the last of August, thereby affording good pasturage for bees in September.

In conclusion, I must say that I am well pleased with the plant, judging from this first year's trial; and I venture to say, that the time is not far distant when it will be extensively cultivated for its honey-producing qualities. I expect to plant an acre next spring. Were it possible for me to meet with you at the convention, I would move a vote of thanks to Mr. Chapman for having introduced this valuable plant. It is valuable, not only to beekeepers, but to the florist as well, because it is a very beautiful plant, and so very rare withal.

I remain yours truly, A. E. MANUM.
Bristol, Vt., Oct. 7, 1886.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER.
MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, JAN. 1, 1887.

And God said, Behold I have given you every herb bearing seed, which is upon the face of the earth.—GEN. 1:29.

THE AMERICAN APICULTURIST FOR JANUARY.

We congratulate friend Alley on having given us another number containing so many good things. I am especially pleased with his remarks in regard to procuring good queen-cells, on page 24.

THE BEE-HIVE.

The above is the title of a very pretty and well-gotten-up little bee-journal, for the small sum of 30 cts. per year; and commencing with the April number it will be hereafter published once a month instead of only once every other month. The printing and general get-up of the whole does much credit to friend Cook. We can furnish it with GLEANINGS for only \$1.20 a year.

DIFFERENCE IN CHARGES BETWEEN EXPRESS AND FREIGHT.

A GREAT many times, heavy and bulky goods are ordered by express. When we feel quite certain the party who made the order was thoughtless or not posted, we take the liberty of sending by freight. The following illustrates it:

The goods you shipped me on the 26th of November were received to-day, all in good shape. I am pleased with them; freight was 86 cents, or \$2.00 less than by express. They are heavier than I thought they would be. G. L. HONEYWELL.
Carr's Creek, N. Y., Dec. 8, 1886.

You will notice, the goods were 12 days on the way. Perhaps they might have gone in less than half that time by express, but our friend saved \$2.00 by waiting a few days longer.

ATTENDING STATE AND COUNTY FAIRS.

SEVERAL of the brethren have taken me to task because I, a professing Christian, recommend other professing Christians to mix in with those usually found at such places. If it were a horse-race or a beer-garden, or even a skating-rink, I should be very slow in advising our boys and girls to go.

Our fairs, however, are instituted for educational purposes, and teaching rural and mechanical industries—a sort of education I begin to feel is of just about as much importance as that to be received at schools; therefore I recommend that all Christians should be on hand every time if possible, and by their weight and influence hold on and encourage the good, and crowd out the evil. A part of our Savior's prayer for his disciples was, "I pray not that thou shouldst take them out of the world, but that thou shouldst keep them from the evil."

DR. C. C. MILLER'S BOOK, "A YEAR AMONG THE BEES."

I SHALL have to confess I never got time to read this little book thoroughly until while on the cars on my way to the Michigan Convention. I put it in my overcoat pocket, and I found it in more ways than one a blessing. It is *extremely* tiresome for me to be obliged to sit in a car-seat while riding evenings, hour after hour. In the day time I can look out among the homes scattered along the line of travel. Well, I read friend M.'s little book clear through, and I am so very much pleased with it that I wish, during the coming year, to make a review of it through the pages of GLEANINGS, illustrating every point I think worth illustrating, by appropriate cuts. When friend M. reads this editorial he must understand that, if he has any objections to make against my so doing, he must speak quick, or he may get into print more than he expects, and before he knows it.

IS THE NECTAR OF THE FLOWERS MATERIALLY CHANGED BY BEING GATHERED BY THE BEES?

My attention has been called to the fact that on page 881, Nov. 15 issue, where I say sugar syrup fed to the bees will be sugar syrup still, I am in apparent contradiction with what Prof. Cook says in his Manual in regard to the same matter. My reply is this: Prof. Cook does say there is a slight difference in sugar syrup, or nectar of the flowers, after having passed through the honey-gathering apparatus of the bee. I insist, however, that this difference is so slight that my remarks are in general true. I have fed bees sugar syrup, and made them fill sections. The product was beautiful to look upon, but everybody pronounced it sugar as soon as they tasted it. I have also by accident fed syrup a little burnt. Now, even though it remained in the hives six months, the burnt taste was just the same as when the syrup was made. Furthermore, I have melted candied honey, and fed it to the bees to finish out unfilled sections. Now, this melted candy honey, even though perfectly sealed up in the combs, candied again almost at once, so that you could tell at a glance the honey gathered directly from the fields from that which had been fed to the bees to finish out the sections. I could mention many more experiments that indicate that the article fed to the bees passes in and out of their honey-gathering apparatus without any change, practically speaking; therefore neither Mrs. Cotton nor anybody else can feed bees sugar so as to induce them to make honey; and those who have tried feeding bees glucose, have found simply glucose stored in the combs, and nothing else, so far as taste is concerned. In some cases there may be a slight acid taste perceptible after nectar has been gathered by the bees from the flowers, but not enough to be worthy of much comment, in my opinion.

THE number of subscribers up to date numbers 6079.

MYSELF AND MY NEIGHBORS.

AS you will notice, this department is to be hereafter in the first issue of the month, in order to divide up my friendly talks to you a little more.

MATTER FOR GLEANINGS.

As usual at this season of the year, a great amount has accumulated. We hope the friends will be patient, therefore, if their communications should not be presented for three or four issues after they have been sent in.

THE CONVENTION AT ALBANY.

I EXPECT to be on hand some time during Tuesday, the 11th, and to be present during the three days' session. As this will take me so near the city of New York, I shall probably make a call there, and try to write up such items of interest as I may find for the readers of GLEANINGS. As the locality is a central one for many of our veterans in bee culture, we hope to see a large attendance.

DATING BEE-KEEPERS' CONVENTIONS.

It seems a little unfortunate that the Ohio Convention should be exactly on the three same days as the convention in York State, which so many of us have been proposing to attend. Can't our friends who have these matters in charge have an understanding, so we may avoid having them come on the same day? Surely our winters are long enough. My engagement to attend at Albany will, of course, prevent my being at Columbus, but Ernest will be there even if it is bad for us to be both away at once.

KIND WORDS.

It seems as if the kind words from the readers of GLEANINGS this year exceeded any thing we ever received during any former year. Over and over again have I thought this or that good friend must certainly have such an answer as he deserves, forthwith; but when so many of them came it began to be out of the question; and when I talked with the subscription clerks about it, they said it was all they could possibly do, even by working over hours, to get the names on the list, let alone replying to letters. And now I want to say to you all, may God bless you all and reward you! These words of friendship and encouragement are not forgotten; and if I can not get time to reply to each one of you personally, I can remember you in my prayers. May he send a happy New Year to you all.

SHIPPING QUEENS FROM THE SOUTH DURING WINTER MONTHS.

In response to an advertisement of Miss Nellie Adams, seen in another column, we sent for a queen, partly to test her ability in mailing queens during cold weather, and partly because we desired a queen for a queenless colony in an observatory hive. We are glad to announce to our friends that the queen shipped from Florida arrived in Medina in good condition, and only one bee dead. This, too, was when we had quite a cold snap of weather—so cold, indeed, that on opening the cage the queen and her attendants were stiffened with cold. They soon revived, however, on exposure to warmth. It is an interesting question how long a few bees may remain stiffened during shipment, and yet be revived on arrival at their destination. We are glad to make this announcement in favor of our friend Miss Adams, even if it does savor a little of free advertising.

SPECIAL NOTICES.

WE will pay 20 cts. each for May GLEANINGS, 1875. Remember, 1875, and not 1876.

DISCOUNTS FOR JANUARY.

REMEMBER our discount for this month will be 4%; and we have decided to let this apply to all goods of whatever nature. Please remember to have your orders in before the month is gone, if you wish to avail yourselves of this offer.

CHANGE IN PRICE.

SINCE E. L. Gould's advertisement was printed on page 2, we have received from him the following card, taking the place of the advertisement.

The price for Chapman honey-plant seed is as follows: $\frac{1}{2}$ oz., 40c; 1 oz., 80c; 2 oz., \$1.50; 4 oz., \$2.00; 8 oz., \$3.00. E. L. GOULD. Brantford, Can.

BOSTON MARKET LETTUCE-PLANTS.

WE have a beautiful stand of nice little plants now in our greenhouse; and in order to test the matter of sending them safely by mail, we will send 10 plants for 5 cts.; 100 plants for 40 cts.; and if they don't reach you in good order there will be no charge. These plants are from seeds from selected heads of our own raising.

HOW TO ORDER SEEDS WITHOUT WRITING A LETTER.

WE can furnish, on application, a sheet of paper containing the matter on pages 4 and 5. Take this sheet, and with a pencil mark around the seeds you want. Inclose the cash to correspond, and we will know just what to do, and you need not write a word unless you choose, except your name and address. Our complete catalogue of seeds and implements will be out in a few weeks.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column. 3tftd

"BEE-KEEPERS' ADVANCE"

Is a monthly journal of 16 pages, 25 cts. per year. Clubbed with GLEANINGS for \$1.15. Sample copy sent free with our illustrated catalogue of supplies. Don't forget to send name and address on a postal to
JAMES B. MASON & SONS,

CONVENTION NOTICES.

The Northeastern Mich. Bee-Keepers' Association will hold its fifth annual meeting, Wednesday, Feb. 2, in the Common-Council Rooms of Bay City. W. Z. HUTCHINSON, Sec.

The Wisconsin State Bee-Keepers' Association will meet in the Capitol, at Madison, on Thursday, Feb. 3, at 9 A. M. I think no argument is needed to show that these conventions, well attended and properly conducted, will be a source of profit to the bee-keeping fraternity, and pleasure to those who attend.

The State Agricultural Convention will be in session at the same place from Feb. 1st to the 4th inclusive, with a very interesting programme. The papers and discussions of this convention will be of interest to everybody.

Hotel accommodations abundant, at any price from one to three dollars per day, and return tickets over the principal roads at reduced rates.

We especially desire the attendance of those bee-keepers who have learned it all as teachers; we more especially desire the presence of those who have not learned it all, for they make the best of pupils. F. WILCOX, Sec.

C. M. GOODSPEED,

THORN HILL, ONONDAGA CO., N. Y.,

Furnishes any newspaper to single subscribers, away below the usual club rates. Our list comprises all the leading papers, and is the lowest-priced list in the field. Alsike, bees, queens, poultry, and small fruit. Write for 20-page catalogue. Mention this paper.

Recent Additions to the Counter Store.

THREE-CENT COUNTER.

- 1 PLATE, 6-IN., glass, crystal or colored | 28 | 2 60
A little beauty, and handy for many purposes.
- 2 SHOE AND GLOVE BUTTONER | 28 | 2 50
Both on a key ring. All for 3 cents.
- 2 BRASS FERULES for tool-handles | 25 | 2 40
Dozen pkgs., 5-16, 6-16, and 7-16. You may have a dozen assorted or all of one size.
- 2 PATTY-PANS, ROUND, 5-IN | 20 | 1 80
Just right for small pies or maple-sugar cakes.
- 2 PENCIL, LEAD, with rubber cap; 20 cts. per dozen | 17 | 1 50
This is a plain cedar pencil, with an inserted rubber cap.
- 2 SLATE-BOOK, 6 pages and pencil | 25 | 2 40
Much smaller than the 5-cent ones, but very handy.

FIVE-CENT COUNTER.

- 1 SENSATION PICKLE-DISH, colored glass | 48 | 4 75
This is a beauty. The pattern is much like "polka dot."
- 6 SENSATION SALT OR PEPPER BOTTLE | 46 | 4 50
With nickel top; same pattern as the pickle-dish, and colored glass. The top being nicked, it will not tarnish.
- 2 SLATE-BOOK, 6 pages and a slate-pencil | 40 | 3 80
Very handy for taking notes.
- 2 PROPELLING PENCIL | 36 | 3 50
This is a very handsome lead-pencil, black-enamelled, and nickel ends. The point of the lead may be protected, or a new one inserted, when the first is worn out; 6 extra leads in a neat wooden box, for double above prices.
- 2 BRASS FERULES for tool-handles | 40 | 3 80
Dozen pkgs.; $\frac{1}{8}$, 11-16, and $\frac{3}{4}$. We have obtained some more of these that are stronger and nicer, and you may have a dozen assorted, or one size, just as you choose.

SEEDS

Tested, sure to grow. 130 kinds of POTATOES, all the new Beyer Plants. Superior Stock. Prices low. Catalogue free. It will pay to get it. FRANK FORD & SONS, Ravenna, O.

What Mr. Beyer says:

"Please best thanks for the splendid seeds received from your firm. It would be a rather lengthy list if I should name all, but will say that amongst 33 first, and 3 second premiums awarded me at our fairs in Northern Indiana and Southern Michigan, 28 first premiums were for vegetables raised from your seeds. What firm can beat this?" AUGUST BEYER, So. Bend, Ind.

Seed of this quality I am now ready to sell to every one who tills a farm or plants a garden, sending them FREE my Vegetable and Flower Seed Catalogue, for 1887. Old customers need not write for it. I catalogue this season the native wild potato. JAS. J. H. GREGORY, Seed Grower, Marlborough, Mass.

HONEY COLUMN.

CITY MARKETS.

DETROIT.—*Honey.*—The market continues dull, with no change in prices. Best white comb, 12½; Buckwheat and fall flowers, 10@11. Extracted offered at 6@8. *Beeswax*, 23c. M. H. HUNT, Jan. 10, 1887. Bell Branch, Mich.

PHILADELPHIA.—*Honey.*—White clover, fine, 14@15; white clover, fair, 12@13; buckwheat, fine, 11@12; same, fair, 9@10; one and two pound glass sections. Extracted, 6@8, as to quality. *Beeswax*, 20@23, as to quality. Jan. 10, 1887.

PANCOAST & GRIFFITHS,
242 South Front St., Philadelphia, Pa.

ST. LOUIS.—*Honey.*—Market is dull; choice comb, white clover, 1-lb. sections, 12@13. Other grades in sections, 10@11. Broken comb, 6@8; white clover, extracted, in cans, 5½@6. Southern in bbls., 3@5. California extracted, in cans, 4½@5, for dark, or amber; 5½, choice white sage. *Beeswax*, 21@22, as runs; 25, selected. W. B. WESTCOTT & CO., Jan. 10, 1887. 108 and 110 Market Street.

CLEVELAND.—*Honey.*—This market has been very dull the past two weeks. Prices are unchanged; best white 1-lb. sections sell at 13c; 2d quality, 10. Best white 2-lbs., 11@12; 2d, 8@9. Extracted is very dull at 6c. *Beeswax*, 25c. A. C. KENDEL, Jan. 10, 1887. 115 Ontario St., Cleveland, O.

CINCINNATI.—*Honey.*—Nothing new of importance since last report. Demand is very slow for all kinds of honey since Christmas, and occasional concessions have to be made to effect a sale of comb honey.

Quotations have to be made as heretofore; 3@7 cents for extracted honey on arrival, and 12@15 for best comb honey, in a jobbing way.

Beeswax.—Demand is good for beeswax, which brings 20@22c on arrival for good to choice yellow. Jan. 11, 1887.

CHAS. F. MUTH & SON,
Cincinnati, Ohio.

BOSTON.—*Honey.*—Demand very light since the holidays, and we quote: Best 1-lb. white clover, 13@14; same, 2-lb. sections, 11@12; California comb honey, 10@12. Extracted, 5@7. *Beeswax*, 24c.

BLAKE & RIPELY,

Jan. 10, 1887. 57 Chatham St., Boston, Mass.

CHICAGO.—*Honey.*—Dullness prevails in the honey-market; no change in values since last quotations.

R. A. BURNETT,

Jan. 10, 1887. 161 So. Water st., Chicago, Ill.

NEW YORK.—*Honey.*—There is no change to note in our honey market. The demand is limited, and prices remain unchanged. The finer grades of white honey are getting exhausted, but there is any amount of the poorer grades yet to be disposed of.

Jan. 10, 1887. THURBER, WHYLAND & CO.,
New York, N. Y.

FOR SALE CHEAP.—4500 lbs. choice white-clover honey in 10 and 25 gal. kegs and in 48-gal. bbls.; also 2500 lbs. very fine Spanish-needle honey in 25-gal. kegs and 48-gal. bbls. Will send samples on receipt of 2-cent postage-stamp for each.

EMIL J. BAXTER, Nauvoo, Hancock Co., Ill.

FOR SALE.—2000 lbs. best clover honey in Root's "raised-cover pails." One set, 30½ lbs., \$2.50; 4 sets, 122 lbs., \$9.25. Boxed, they ship same as bbls.

OLIVER FOSTER, Mt. Vernon, Iowa.

BEE-KEEPERS' MAGAZINE,

22tfdb

BARRYTOWN, N. Y.

Headquarters in the South.

FACTORY OF BEE-HIVES, ETC.

EARLY NUCLEI, ITALIAN QUEENS.

NINTH ANNUAL

CATALOGUE FOR 1887 NOW READY.

P. L. VIALLO, Bayou Goula, La.

FOR SALE. One Barnes combined scroll and circular saw. Has fourteen circular and ten scroll saws, one cutter-head, two mandrels, three gauges, one sawset, one emery wheel, all in running order; will sell for \$35.00, which is about half cost. Address **E. C. APPLIGATE,** 1-2d Poplar Flat, Lewis Co., Ky.

ATTENTION!

SECTIONS, BEE-HIVES, HONEY-BOXES, FRAMES, ETC.

LARGEST FACTORY IN THE WORLD.

Best of goods at lowest prices. Write for free illustrated Catalogue. **G. B. LEWIS & CO.,** 1tfdb Watertown, Wis.

TERMS: \$1.00 PER ANNUM IN ADVANCE; 2 Copies for \$1.50; 3 for \$2.75; 5 for \$4.00; 10 or more, 75 cts. each. Single number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid. In the U. S. and Canadas. To all other countries of the Universal Postal Union, 18 cts. per year extra. To all countries NOT of the U. P. U., 42 cts. per year extra.

Vol. XV.

JAN. 15, 1887.

No. 2.

T. P. ANDREWS' APIARY.

A FURTHER DESCRIPTION OF THE SAME.

FRIEND ROOT:—Replying to your request for fuller information in regard to the cut of my apiary in GLEANINGS, I would say that the photograph from which the cut was made was taken with a lens not adapted to this kind of work, as it considerably diminished the apparent size of objects in the background, thus exaggerating their apparent distance. In reality, those rows of hives that look so long are only about $5\frac{1}{2}$ rods long. The apiary is laid off in squares, by streets eight feet wide, crossing each other at right angles. The one broad irregular street shown in the cut running from east to west is an error of the engraver. The squares between the streets are one rod square, and contain sixteen hives—four rows of hives each way. This puts the hives a little more than five feet from center to center. I have not found that the bees mistake their hives to any appreciable extent.

The honey-house is 14 by 18 feet. The south side is seen in the picture. The northwest corner of this building is occupied by a honey-tank holding 5000 pounds. It is securely made of 2-inch pine planks; is lined with tin, and rests on a strong frame, high enough to draw off the honey into barrels or cans. At the south side of this tank stands a four-frame Stanley honey-extractor. The pail in which the honey is carried from the extractor to the tank, stands in a deep rectangular tin pan, which I made several years ago, to use in making fdn. from plaster-of-Paris casts. This pan is to catch any accidental overflow from the honey-pail, and stands

between the extractor and tank. A piece of oil cloth, hanging from the upper edge of the tank, reaches down into this pan, to catch any drip from the pail while being emptied.

A much more convenient honey-house could be built on a side hill by placing the honey-tank on a lower floor, as does friend Christie, of Iowa.

For convenience in getting the full combs to the extractor, and the empty ones away, I have made two openings in the south side of the honey-house, about six feet apart, and one foot above the floor. I also made two sets of rolls, each about eight feet long. They are like ladders with rollers instead of rounds. These ladders are placed so as to project out through the side of the building about two feet, far enough to set a hive on before sliding it in on the rolls. My comb-boxes are simply hive-bodies with a thin bottom nailed on, and covered with a piece of cloth, one edge of which is tacked to one side of the hive, the other edge being tacked to a slender stick which keeps the cloth straight, and holds down the edge. Three of these comb-boxes are placed side by side in the cart, which I will describe at another time, and are drawn out to the hives, and filled with combs. These are taken back to the honey-house, and shoved in on the first set of rolls. The cart is then drawn forward to the next opening, where three boxes of empty combs are rolled out to fill the cart for a second trip to the hives.

Farina, Ill., Jan. 7, 1887.

T. P. ANDREWS.

Many thanks, friend A. You certainly have things very conveniently arranged. We should be glad to have you describe more fully your hive-cart.—In regard to the distance of hives, ours are 7 ft. from center

to center. Besides this, the entrances are turned to all points of the compass. Yet we find that bees in early spring and late in the fall are very often confused as to the exact location of their hives.

BUMBLE-BEES.

SOME OF THEIR PECULIARITIES.

THE question of E. D. Howell, in GLEANINGS for January 1, page 26, brought to my mind the fact that we have in Hilliard, O., an intelligent young man who, about seven years ago, during one season, had several colonies of bumble-bees. His first colony was secured early in the spring, and consisted of a queen and one other bee, seemingly just hatched, and a small bit of comb, not more than three cells, and these contained no eggs or brood, as he now remembers. The nest, bees and all, was placed in a box about eight by twelve inches, turned upside down on a board about two feet from the ground. The entrance was about one-half by two inches. He knew nothing of the inside of this nest-box until late in the fall; and when he opened it, he found neither honey, brood, nor bees, either dead or alive, but one beautiful comb, nearly round, and measuring about seven inches in diameter. The queen was long and yellow, while the workers were much smaller and quite dark. There was a middle class, which seemed idle, and he thinks they were drones. The other colonies were secured later, and seemed to be more or less demoralized all the season, doing their work in an inferior manner, though this may have been their normal conduct and skill, as they were a different bee from the others, being much smaller and much more inclined to sting. Their nests were also empty when opened in the fall.

My young friend gave me many interesting facts about his bumble-bees and about bumble-bees in general. He has never detected the least symptom that they have the swarming habit, and gives it as his opinion that they never swarm. In early spring he usually finds each colony composed of a single bee—the queen—and usually about a dozen eggs, the eggs being something smaller than hemp seed. His colonies kept their houses very clean and tidy; and the fact that they would invariably walk to the edge of the bottom-board, and, with a quick right-about movement, dump their excrement beyond the board on the ground, was a very prominent characteristic; and the queen was no exception in this particular. They also appreciated kind treatment, for while they *never* molested him in the least, they would not allow his younger brother, who would tease them by throwing chips at them, to stay in the neighborhood of their box homes; they would follow him for rods, that they might sting him, and they sometimes got in good work on the young rogue. They always kept a guard at the door, and in the evening this guard would close up, with grass, the entire entrance, except one little place, where she would sit and look out. In the morning this grass would all be taken away, but was replaced again each night. In very hot weather the queen and many of the bees, perhaps all of them, would sit on the bottom-board, outside of the hive. In his first colony he counted at one time as high as nineteen sitting outside at one time; but he had no means of knowing whether they were all the

colony. One day he moved one of the boxes about eight inches to one side, and a bee that came in from the fields tried for about fifteen minutes to find its home, but could not, so he helped it into the hive.

Hilliard, O., Jan. 8, 1887.

J. S. RICKETTS.

Many thanks for the interesting facts you have given us in regard to these bees. We have frequently had them under old bottom-boards in our apiary; and while we pursued our regular work, minding our own business, they gave us no trouble; and, as you may have read in October 1st issue, we could handle them, or pull apart their nest, without their making even a show of resistance or attack. Not so did they behave toward the small boy, equipped with a paddle and a pole to poke their nest up.

MAKING EGGS HATCH WHEN TAKEN FROM THE BEES.

TRANSFORMATION FROM THE EGG TO THE LARVÆ.

EDITOR GLEANINGS:—When first reading your A B C, when I came to that part relating to "Bees," you say that you have "never been able to get eggs to hatch when taken away from the bees," although the temperature was carefully preserved. At that time I had had but little experience in matters of that kind; but being of an inquisitive turn of mind I decided to make some experiments in this direction. However, I put the matter off from year to year until the summer of 1884, when the following experiment was carefully conducted: I placed a sheet of foundation in the center of the brood-nest, and left it there until it was filled with eggs, and a small area of larvæ had appeared on either side. I then removed the comb, and with the point of a pin I drew a line carefully dividing the larvæ from the surrounding eggs; the comb was then placed in the nursery, and left over night. An examination the next morning showed that no additional larvæ had been hatched. I then marked half a dozen cells containing eggs next to or joining the little patch of larvæ. With a little spoon I dipped out the milky food from the cells containing larvæ. I placed this food over and around the half-dozen eggs that were marked. I then replaced the comb in the nursery. Two hours later I made an examination with a glass, and found that, in each of the cells thus treated, larvæ were present, but no development was discovered in cells not treated with the milky food. These experiments were successfully carried on immediately around the patch of larvæ previously formed, for a period of 48 hours, after which no development could be had. I then treated a like number of cells near the outside limit of the field occupied by eggs, and had the satisfaction of seeing perfect larvæ in 80 minutes after supplying the milky food.

Another point worthy of note was the disappearance of the tissue inclosing the larvæ after the action of the milky fluid. From these experiments it would seem, first, that bees' eggs do not hatch, but are liberated by the action of the acid contained in the food for young bees, the larvæ having no means of biting or breaking his way out of the prison wall that surrounds him. Second, the disappearance of these tissues results from the neutralizing or destructive action of the acid upon the same. Third, that larvæ will stand 48 hours of confine-

ment, without physical development. This fact will perhaps account for the discrepancy of time in the hatching of queens being from 16 to 18 days.

Siam, Ia., Dec. 25, 1886.

R. B. ROBBINS.

Your experiments in making the queen's eggs hatch are very interesting. I have carefully looked through Cheshire's book, "Bees and Bee-keeping," upon this matter, but can not discover that he touches upon the point you bring out. If your experiments were carefully conducted it would seem that the egg, in order to hatch, requires the milky food; but as to whether this food absorbs the shell, or covering, of the egg, I must confess that I feel a little uncertain yet. Perhaps Prof. Cook, or Prof. J. Comstock can give us some light upon this matter.

A FEW POINTERS FROM THE OHIO STATE CONVENTION.

A FEW NOTES FROM ERNEST.

JAN. 14. I have just arrived home from the State Convention, held at Columbus, Jan. 11, 12, and 13. As we are about to go to press with this issue, I will throw out a few hints which I gathered there, in advance of the regular detailed report which will be sent in for next issue by the secretary.

PREVENTING THE GRANULATION OF LIQUID HONEY.

Our readers will remember that we have once or twice had occasion to refer to the liquid honey sent us by Mr. Goodrich. This honey still retains its beautiful transparency, although it has been subjected to varying temperatures. Mr. Goodrich, the producer of said honey, was at the convention. By request he gave his manner of keeping his honey, which, in brief, is essentially as follows:

The honey is extracted, and drawn into sap-pails where it is temporarily covered with cloth. To prevent its granulation he heats the honey in the pails to a temperature of about 120 or 130 degrees. This he does by placing a number of said pails, filled with honey, in a vat or tin trough of hot water, heated to the proper temperature. There is thus no danger of overheating the honey. While the honey is being heated it is stirred, so that every portion may be heated alike. He ascertains the proper temperature by inserting a thermometer in the honey itself, and not in the water, as we should naturally suppose. The honey is then put in Muth's 2-lb. bottles.

Of course, the idea of heating honey to prevent granulation is not new; but the manner of doing it will, I think, be valuable to some of our readers. Heating honey is apt to take away some of that delicate flavor; but I think all who taste the Goodrich honey will acknowledge that it is as fine as the finest.

FULL SHEETS OF FOUNDATION, VERSUS STARTERS OR EMPTY FRAMES.

I was surprised to see how many reported favorably in regard to frames with starters

only. I then explained the Hutchinson plan, and a number thought it seemed reasonable. No less authority than our good friend Mrs. Jennie Culp favored full sheets of foundation, notwithstanding, and she was backed by Mr. A. S. Goodrich.

WHAT A WOMAN CAN DO.

As you may guess, Mrs. Culp, of Hilliard, O., was at the convention, and I hardly need say that we all enjoyed hearing her tell of her experiences with the bees. Her kind face, and pleasant manner of speaking, make her one of the welcome members of the convention. Indeed, I think it is not too much to say in her favor, that I doubt if there are many bee-keepers among the sterner sex who are her peers as honey-producers, even though she is nothing but a little woman. Let us see: She took about 8000 lbs. of honey last season, and increased from 40 to 65 colonies. Her average per colony was, as you see, 200 lbs. She did all this work unassisted, with the exception that she got her pupil, J. S. Ricketts, to help her a few hours on one or two days. Finally, in the midst of the honey-flow, when she discovered that her strength was not equal to her energy, she left the apiary and went to camp-meeting to recruit up. One of the members of the convention then asked her why she did not get some one to help her, and thus have secured a very large average per colony.

"Why," said she, "I couldn't get anybody to help me, either for love or money; what could I do?"

She then stated, that, if she had not had the "light wheelbarrow sold by Bro. Root," she never could have handled those heavy crates as she did. Her honey has been selling for 16c for extracted, and 18c for comb honey. She mentioned one instance which I will relate here:

She had taken so much honey from one particular colony (nearly three hundred pounds) that she marked on one side of the hive, "I shall not expect any thing more from you this season." This was toward the close of the honey-flow, and she feared to drain it too closely. She had, however, left the surplus-receptacles on the hive. "A few days after," said she, "I thought I would just peep in and see what they were doing." She found it full of honey. On taking off and weighing, the scales showed 95 lbs. of honey.

These facts were not told us by the lady with any spirit of boasting—in fact, it was with some difficulty that we were able to get her to tell how much honey she had secured from the bees the past season. She has a good locality for bees, but I believe her management has a *great deal* to do with her success.

There are many other things that I should like to speak of; for instance, Mr. J. W. Newlove's manner of preventing, to a large extent, the swarming fever; Mr. Frank A. Eaton's method of inducing bees to go into sections, etc.; but I fear I should be encroaching upon the secretary's report. I believe, however, I have enlarged upon some things of which the nature of a report would not permit.

MR. T. F. BINGHAM.

His Visit at The Home of the Honey-Bees.

SMOKERS, SHALLOW HIVES, ETC.

MR. T. F. BINGHAM, of smoker fame, on his way to the convention at Albany, stopped off at Medina, partly on business and partly for a visit. I will say, at the outset, that whenever one of the old veterans in bee-keeping finds it convenient to visit the Home of the Honey-Bees, so-called, I regard it as a special privilege to show him about, and ask him all the questions I can. Whether he be a supply-dealer or not, he is at liberty to appropriate any idea he may find useful to himself, even if he should intend to use said idea at future date in competition to our business. This has always been our policy; and while we may sometimes have suffered in consequence of this kind of competition, taking into consideration the little hints and ideas we gain in return—we never lose.

Mr. Bingham and ourselves, for a number of years back, have made and sold smokers, and, as a matter of course, our goods have come more or less into competition. As was to be expected, in our conversation yesterday we freely discussed the relative merits of the Clark and the Bingham smokers. The inventor of the latter, after noting the manner in which we made the Clark, kindly offered suggestions, or, if you please, "short cuts," in its manner of construction; and while we *may* use said suggestions, we shall respect the principle of his smoker, which, indeed, Mr. Bingham gives us the credit of doing. When we were discussing this smoker question I inquired what he thought of the shaving fuel which Mr. Heddon recommended in his book, and which had been talked of lately in the journals.

"Well," said he, "I prefer hard-wood chunks to any thing else."

He then explained that the shavings were too apt to cause sparks, and, besides, would not last as long as the hard wood. He stated that it was a prevalent opinion among bee-keepers that rotten wood is the fuel for smokers. This opinion he regards as a great mistake. The rotten wood will not only burn out too quickly, but is open to the objection of shavings; namely, a too frequent cause of sparks.

While no doubt friend Bingham is correct as regards the proper fuel for his own smoker, yet with the Clark the difficulty with sparks from rotten wood and shavings is to a great extent obviated, I think, by virtue of the cold-blast principle. Of course, I am not forgetful of the fact that the Bingham possesses good features which the Clark has not. I will not, however, take space to discuss it here, but defer it until next summer, when I propose trying both smokers side by side, and I hope, letting them stand solely on their own merits.

I asked Mr. Bingham how long he could make his smoker last, without going out, charged with the hard wood. If I am correct, his reply was that it would last *all day* without refilling, and that it would give him smoke just when he wanted it. This, surely, is about all that could be desired. But it

seems that Mr. Heddon, his "friend," Dr. Miller, and others, prefer the shavings. Perhaps, however, these latter gentlemen have not acquired the knack of burning hard wood.

SHALLOW HIVES.

Knowing that our friend Bingham for so many years back has used, and very successfully, too, the shallow closed-end frame ($6\frac{1}{2} \times 23$ inches), I took the opportunity to question him in regard to the working and merits of such a frame, with which he says he has had an experience of nearly 20 years. A few facts from him will be of interest just now, when the discussion of shallow frames is before bee-keepers.

Mr. Bingham's frame is $6\frac{1}{2} \times 23$ in., as already given, with closed end-bars $1\frac{1}{2}$ inches wide. This frame has no bottom-bar. The top-bar is a stick, $\frac{3}{4}$ inch square. At each end of this is nailed the closed end-bars, the stick being so nailed that one of the corners will form a comb-guide.

One would naturally suppose that a frame of this description would hardly be secure enough, and that the end-bars, on account of the absence of the bottom-bar, would be easily knocked out of "whack," as the expression runs; but Mr. B. assured me that such was not the case. Eight of these shallow frames, or any other number as convenience may require, are held securely together by compression. This is effected by a well-known principle; namely, a wire loop, or link, each end of which is hooked over a screw-head. A little stick, equally distant from each screw-head, is made to spread the wire taut.

It did not seem to me that such a contrivance would hold securely enough; but Mr. Bingham assured me that he had used it a good many years. To satisfy myself more fully I took seven shallow-depth closed-end frames which we happened to have on hand, and looped them together, as described above. I dropped the seven, as thus secured, on the floor, and scuffed them about with my feet, and yet they held together.

Mr. Bingham told me he could invert his brood-chamber if he chose to do so, but that he did not find it necessary. If I remember correctly, I believe he said he did not even alternate the sections of his hive, although it could easily be done. I then asked if, from his experience, it were practicable to handle these shallow hives instead of frames. He replied, that it was possible to a very large extent. He told me he had not handled the frames of some hives for several years; that he could perform many of the needed operations by simply handling *hives*. By grasping one of his shallow sections, and holding it up to the light, he could hunt out the queen-cells on the several frames at once. He, said, that in a shallow brood-nest, the exact location of the queen can often be determined by the peculiar commotion of the bees toward a common center. Then, if he chooses to catch or view her majesty, he loosens and spreads apart the frames, and selects the one whereon she is to be found. He can also, when occasion requires, shake a large part of the bees from whole sections at once. In short, our readers will see that

Mr. Bingham verifies Mr. Heddon's statement as to the possibility of handling *hives* instead of *frames*.

Although the construction of the Bingham hive differs in detail from the Heddon, yet, in a few of its fundamental principles, the former is similar; as, for instance, closed-end shallow frames, held together by compression; and the possibility of handling *hives* instead of *frames*.

I hope I am not trespassing on any of Mr. Heddon's claims, as I am sure Mr. Bingham concedes to Mr. Heddon the right of his invention. Mr. B. has told me that he is glad that Mr. H. has brought out his invention.

In conclusion, I desire to say that all who shall be so fortunate as to make Mr. Bingham's acquaintance will find him a pleasant conversationalist—in short, a gentleman. While he has a keen sense of justice, and his own rights, they will, I think, find him disposed to be fair.

EXTRACTED HONEY.

E. FRANCE'S VS. HEDDON'S METHOD.

HAVING read Mr. Heddon's article in GLEANINGS, Dec. 1, entitled, "Extracted Honey," etc., I arise to make a few remarks on his system as he has it laid out. I understand he works to a large extent for comb honey and considerable extracted honey. Now, as I am in the extracted-honey business quite largely, I study carefully every thing I can get on the subject, especially from as good authority as Mr. H.; but I don't see how it is possible for me to wait until the honey-season is over, and then do our extracting. We possibly could work our home yard in that way, but I don't see how we can work our five yards, away from home, by his plan, as we have nothing but a tent to work in, and that we carry with us. We extract four and sometimes five times at each yard, taking out from 1500 to over 2000 pounds each time from each yard. Now, to tier up combs to hold the honey, we should need to have combs to hold 9000 pounds of honey in each yard. As about 2000 pounds of honey would be required to winter each yard, we should have spare combs in each yard to hold 7000 pounds of honey, or, for the six yards, spare combs to hold 42,000 pounds (which was our surplus for the year 1886). As we have no place away from home to store the spare combs where they would be safe, they would all have to be hauled home; and what a time we should have with robber-bees, extracting and fussing with all those spare combs after the honey season is over, which closes with us from the 5th to the 20th of July!

As for the quality of the honey, judging from the reports of my customers, many of them dealers of long standing in the honey-trade, I am led to believe that our honey is A No. 1, and I believe our location has very much to do with it. We are located among the bluffs of the Mississippi, still away from the river, where the hills are dry; and the honey, as a rule, is thick when gathered. Often the honey in new combs is so gummy that it is impossible to extract it and save the comb.

I don't know any thing about Mr. Heddon's locality; but judging from his place on the map he is near the lake, and I should expect the country to be flat, and more or less wet, and the honey may re-

quire tiering up to dry it out—very much more so than among the hills here. Bee-keepers living in a hilly locality extract often, and there is no talk of unripe honey. I know there is no use of so much fussing here to get first-class ripe honey.

Platteville, Wis.

E. FRANCE.

Thanks, friend France. I think it is quite likely, as you suggest in your last paragraph, that the difference in locality has much to do with the matter of ripening honey.

CONVENTION AT ALBANY.

NOTES BY THE WAY.

IT is now Monday morning, Jan. 10, and I am waiting for the train. I have got some postal cards, addressed to myself, in my pocket, and whatever I find of interest I propose to send back to the printers, and have them give you the latest intelligence up to the moment of going to press.

I am now at Cleveland, Ohio. I find that friend Kendel, of the Cleveland Seed Store, seems to be doing a fair business in comb honey. One-pound sections, best, bring 13c; second quality, from 10 to 11c. A lot that looked very fine, he says don't sell, because customers have found the sections inside do not turn out so nice as those packed next to the glass. Do you see how it works, friends? Glass sections do not sell well in Cleveland, unless at a season when no other is to be found in the market.

Mr. K. has an ingenious method of his own invention for testing seeds. A coil of gas-pipe is placed in the fire-box of the base-burning stove that warms the store. Proper attachments carry the pipe under benches near the window. On these benches, small pots containing seed are placed, each pot containing 25 seeds. By counting the number that vegetates, the percentage can easily be estimated. The same coil of pipe warms a tank of German carp that seem lively enough, even in the depth of winter. This arrangement seems to answer every purpose of a regular hot-water warming apparatus; but altogether it did not cost over \$10.00, aside from the cost of the pipes, which was about \$40.00. A sort of "stand pipe," with which the ends of the coil are connected, allows room for the expansion of the water. By means of such an apparatus, any part of a building may be warmed, and the consumption of coal is but little more than what is ordinarily needed.

I found lettuce from Cincinnati already on the Cleveland market. It is a small variety, that does not make a head. It is very crisp and tender, and seems to suit this market best. I succeeded in selling the crop of Boston Market in our greenhouse at home. I was pleased to find at friend Kendel's the seed of this Cincinnati lettuce, and a package was mailed back home to be sown in the greenhouse at once.

At the office of the *Ohio Farmer* I was pleased to make the acquaintance of the editor, M. J. Lawrence. Their circulation has now become so large they keep two large Campbell presses running constantly. Quite

a goodly company, both of men and women, assist friend L. in getting out weekly one of our best agricultural journals.

I am now writing on the cars, *en route* for Albany.

These fast trains do not stop for supper, and the dining-room car is therefore the only chance. A dollar for supper seems even worse than a dollar for a dinner; for who wants to eat a "dollar's worth," or any thing like it, just before going to bed? However, as I am employed by the readers of GLEANINGS to travel and take notes, I thought I would see if I couldn't get something out of even a "dollar supper" for their benefit, and I got it. What do you think it was? Why, this: I found on the bill of fare, "Beefsteak and Mushrooms;" and as I had noticed in the eastern market reports mushrooms at \$1.50 per lb., I have been getting the mushroom fever. They are to be raised in winter in a warm cellar or cave. Mammoth Cave is said to answer nicely. But suppose I get some raised how shall I know when they are just right, and fit for market? Why, if they are just like those I had on the dining-room car, to be sure they are right.

Well, it is after supper, and mushrooms are tiptop. They taste a good deal like those that grow in the fields in summer time. I believe there is money in them, grown in winter. "Gardening for Profit" tells all about growing them.

A farmhouse is on fire this bitter cold night. The roof is just falling in as we rush by. The family doubtless fired up the stoves strong to keep out the frost, and this is the result. Home, and all its contents gone. Take warning, friends; look to your flues and chimneys. When the weather is severe, and you are firing heavy, keep watch of things. Fathers and mothers, look after your homes and little ones.

Continued next issue.

FIRST-CLASS COMB HONEY.

THAT WHICH HAS REMAINED LONG ON THE HIVE,
THE BEST.

I HAVE just been reading what friend Heddon says, on page 882, about extracted honey. I believe he is correct, and also that what he says in regard to extracted is equally true of comb honey.

Friend Root, on page 77 of the A B C book you say, "Very white new comb honey is seldom of the fine, pure, sweet flavor of honey that has been a long time capped over, such as is found in the dark-looking comb." You also tell us about that honey which you left on the hives until winter, and then cut out of the frames, which was the nicest, richest honey you ever saw or tasted. You don't get much of such honey now. No, the most of our comb honey now is taken from the hives as soon as finished, to prevent its being soiled; and the consequence is, a large part of the honey found in our markets is very white and nice-looking; but when it is eaten it doesn't give satisfaction. The fact is, it is nothing more nor less than green honey. If you were buying for your own use, you would not buy such honey. I think you would get that which is much better, except in looks, for from 2 to 5 cents

per pound less. I could not help thinking of this when you spoke of that "snowy white" honey, in GLEANINGS recently, which you were selling for 18 cents. Such honey will sell well, but it will not sell next year's crop. With such honey it would be difficult to develop a market in villages and country places; people will buy it for awhile, but will soon get sick of it, and "stop short off," as friend Martin says. I think there never will be an overproduction of first-class honey, either comb or extracted. The trouble is, only a small part of the honey produced at the present day is first-class in every respect.

I believe this is an important matter, and I think that, if the brethren would all take hold and "pull together," instead of sitting down and crying overproduction, we should soon see an improvement in the honey-market.

O. G. RUSSELL.

Afton, N. Y., Nov. 29, 1886.

Thanks, friend R. While I think you are correct in the main, I can not think that nice white honey that has been taken from the hive as soon as capped is "green" or unripe honey. We have been selling just this class of honey, and it has always given good satisfaction. I believe, however, as stated in the A B C, that honey long capped over has generally a little finer flavor; but whether it were better to sacrifice the snowy whiteness of our market honey for this slight improvement in flavor, I have my doubts.

MANIPULATING FRAMES.

POND'S METHOD.

I E. POND, Jr., has got hold of a correct principle in handling frames for the production of comb honey. What is the use of having movable combs if we do not take every advantage of so great a principle? I am pretty sure that another season will demonstrate the fact to the satisfaction of every one who will take the trouble to experiment. To illustrate his plan: I will state my practical application of it by describing my hive. I use the ten-frame Gallup hive, frames $11\frac{1}{2}$ in. square. Hives inside, measure $12 \times 12\frac{1}{2}$ and 15 inches long; the frames hang crosswise; and the 10 frames, spaced $1\frac{1}{2}$ inches, just fill the 15 inches. Now, in the opening of the clover in the spring, I just shove the ten frames up and put in a wide (2-in.) frame at one end, filled with 4 sections and fdn. Then I have ten brood-frames in the space of 13 inches. This, I think, is about right. At the proper time I set on top my case of pound sections, and so work for pound section honey till the close of the season, or about the last of July. I then take off and put away all top cases of 1-lb. sections. I now open the brood-nest, take out the wide frame at the end, and I find four $1\frac{1}{2}$ -lb. frames of nice clover honey—six pounds or more, No. 1 clover honey. I now proceed to pull back or spread the ten brood-frames on the 15 inches, which puts them $1\frac{1}{2}$ inches from center to center, and they will find enough during the fall flowers to build out and fill up for winter. We never get any surplus here in Southern Missouri in the fall, but they get enough in September to winter well. I should like to hear others report on this plan.

W. H. RITTER.

North Springfield, Mo.

A CHAPTER FROM REAL LIFE.

FORGETTING TO CLOSE THE DOOR OF THE HONEY-HOUSE, AND THE CONSEQUENCE.

IN the bill of goods I ordered of you were a lot of nest pails. I ordered them for the purpose of extracting honey. There was but little call for the large pails, while I supposed they would sell the best. I could not dispose of them for what they cost me, consequently I have quite a number on hand. I found that quart pails with 3 lbs. of honey sold by far the most readily, and I ordered a gross of them from Fort Wayne. They cost a little less than 5 cts. apiece, including freight, and in them I sold the remainder of my extracted honey very readily for 30 cts. each, including pail.

I had a ton of honey, including section and extracted. I commenced selling sections at 14 cts., but most of them for a shilling, and the dark, or fall honey, for 10 cts. I had 24 swarms in the spring, and put 54 in winter quarters. Though they apparently had honey enough for winter stores, they were dying badly, and some were affected with dysentery.

I was compelled to move my bees to keep good friends with my neighbor who owned land but a few rods from where they were, and I would not have a quarrel with my kind neighbor for the worth of the bees.

ITALIANS, BLACKS, OR HYBRIDS—WHICH?

I have Italians, hybrids, and blacks, in my apiary. As honey-gatherers, I know no difference. Some of the blacks are the most docile bees I have, while others of the Italians and hybrids are too vindictive to handle without a quantity of smoke. I have had but one swarm ruined by worms in many years, and those were blacks. After filling nearly 100 sections, they took to swarming, till but few bees were left; then the robbers ruined them, and the worms made a clean sweep of them. I would not care for Italians, if I did not hate to hunt black queens so badly.

JUST HOW I GOT CAUGHT.

It has been a very busy season with me, putting up and repairing buildings, with an abundance of work on the farm; and being of a nervous temperament (some like friend Root) I often get in a hurry, and from a fast walk I would get into a run. I had been taking off sections, and, for want of time to put them on the shelves, I packed them helter-skelter on the floor of the honey-house till a more "convenient season" to put them away. It was near the close of the honey season, and bees got crazy at the slightest smell of honey. In my great hurry one day I went into the honey-house for something; and when I went out I slammed the door after me, not thinking but it was fast, and went about my business. After awhile, wife called me, and said I had better look and see what the bees were doing. I did look, and, sure enough, there were bees enough to make two good swarms, in the house, on the windows, and piled on the sections; and when I went in they "piled" on me too. If ever a fellow was stumped, I was. But necessity always had been the mother of invention; and if it failed this time it would be the first with me. I said, "Wife! I'll kill them with sulphur," and at it I went, and made smoke enough, as I thought, to kill any thing. I closed the door, and left them to their fate. In half an hour I came

back and found but few dead. I thought best to renew the sulphur smoke. I did so, but it almost choked me, and I slammed the door after me, and left them a second time to their fate. After awhile I went back and found the door standing wide open, and such piles of bees I never saw piled into one room. I said, "What shall I do? what shall I do?" and what would you have done, friend Root?

I have read somewhere, that, if at first you don't succeed, try, try again. I said, "Wife, I have got to kill all my bees" (57 swarms). But another thought struck me. I had seen bees smoked to death, so I put in kettles and iron dishes, after making fires in them, and piling them full of trash, just as we used to smoke mosquitoes when it was all woods around us, and I was careful to shut the door this time. The house was made tight, intended to keep out the moths and millers, and the smoke soon began to tell seriously on the bees, but I let them sweat till not one could fly, and I could not stand it longer than I could hold my breath. I let in what air I could through the window-screen, occasionally opening the door; and when the smoke cleared away so I could move the sections into the closet, brushing off the dead bees, it was a fearful-looking place.

I said, "Wife, I have conquered at last." She said, "You look as if you were about conquered too."

You had better believe I was happy. Now you will ask what about the honey (for there was the best part of a ton). Was it not ruined by the smoke? Of course, I supposed it was. At first, for a week or two it smelled too smoky to be salable, but it gradually wore away by giving it all the air I could, till that which was nicely capped had no taste of smoke; but all that was uncapped retained the smoky flavor a long time; but it is all disposed of, except what we need for our family use. I have always been particularly fond of seeing and handling bees; but I pray that I may be excused from handling any more in a honey-house.

La Otto, Ind., Dec., 1886.

E. S. HANSON.

Friend H. wants to know what I would have done under the circumstances. Well, I would not have killed my bees, whatever I did. You say you were happy after you got them all killed. Now, the thought of those murdered bees would not have let me sleep nights had I been in your place; however, there is no use wasting words on that part of it, for they are gone now. I have been through just about the same experience a good many times, and I will tell you how I manage. Of course, the first thing is to shut the door; and, by the way, the latches to the door of the bee-house ought to be so arranged that they shut easily and securely every time. I have often thought that a spring to the door, such as we have on our screen-doors, would be a good investment, then have the catch so it will fasten the door, no matter where or how the door may be left. Prevention is better than cure, you know. But if the bees do go in because of the door being fastened open, or something of that sort, shut all the doors and windows securely, so that no more can get in. When the bees collect in a large quantity on one of the windows, raise the window, and with a brush broom, or something similar, get out as many as possible.

When another lot collects, let them out in the same way, and in a very little time you can have every bee out of your room. In view of such occurrences I would have a good wide shelf just below the window, and keep this shelf clear of rubbish. Then at any time, by raising the window a little you can easily brush out all the bees that have dropped down, so as to keep your house tidy and neat. Where there are only a few sections that the bees can work on I would put them in a tight box or cupboard. Simplicity hives piled up will hold frames of comb or sections of honey very well temporarily. Now, if you want to cure your bees of hanging around the honey-house doors or windows, just let them go in the room and out at pleasure, until they are satisfied there is not a drop of honey to be obtained. If it is during a season when they rob badly, Simplicity hives piled up may be a rather bad arrangement, for bees smell the honey through the cracks. In such a case, cover the pile of hives with a large sheet, or, better still, an oil cloth, such as is used to spread over wagons; or if your room is not large enough, open your bee-tent, and spread that over it. Surplus comb honey ought to be very secure indeed, to prevent bees from scenting it. Friend Heddon and some others have recommended double sheets of wire cloth, with a space between them. This prevents bees on the inside from passing honey through to those on the outside; but whatever way you take to make it secure, don't have any mistakes about it, or you may have such scenes as our friend describes so graphically in the above article.

SEPARATORS OR NO SEPARATORS.

ALSO SOMETHING IN REGARD TO THE WORKING OF HEDDON'S NEW HIVE.

I ENTIRELY agree with G. M. Doolittle, on page 839, that we have been making a move in the wrong direction in regard to separators. Until three or four years ago I think it was pretty well settled that comb honey could not be satisfactorily produced without separators. About this time a number of comb-honey cases appeared, designed to be used without separators. Some of these were very convenient to use, and, aside from the non-separator feature, were much better than the old systems. These were "boomed" by those favoring them; and from being written and talked about so much it became fashionable to do without separators, and many who really preferred them were ashamed to admit that they could not do without them. Everybody followed his neighbor.

One of the most characteristic traits of the American people is their tendency to popular crazes, a tendency to take up every thing that is new and attractive, and carry it to extremes. Never more strikingly shown than in their amusements—as, for instance, roller-skating and progressive euchre—this tendency has its influence in every department of life. Any business that is more than ordinarily profitable is rushed into, and almost immediately overdone. Bee-keeping is suffering now from just such an inundation on a small scale. But this is a digression.

With all the hue and cry against separators, everybody seemed to think that everybody else was giving them up, and that he must fall into line or be left behind. How the movement against separators was forwarded, may be learned from the way the subject was handled at one of our conventions. After some talk in which the anti-separator men aired their views, while those who favored separators for the most part stood back and listened, the subject was put to vote, and all who could secure marketable honey without the use of separators were asked to stand up. Of course, the most of those who voted at all stood up. Almost any one can produce marketable honey without separators. That is not the question. The report of that convention, stating that three-fourths of its members could get along without separators, was, to a certain extent, misleading, as giving the impression that they were in favor of doing without them. I do not think this was the sentiment of the convention. I think most of them were in favor of separators, and continued to use them, and believe in them to-day. But their half-unwilling admission, that they could get along without separators, no doubt had its influence in inducing others to try the non-separator case, who, finding themselves reasonably successful with it, became loud in its praise.

I can produce comb honey without separators. I have done so successfully. This season I had over 2000 lbs. of honey made without separators. There may have been 25 sections that could not well be crated. Perhaps 200 required a little extra care in crating, while the rest could be put together anyhow without the combs touching. Still, I know that, without extraordinary care, I should not obtain as good results every season; and as I can see no very important benefit to be derived from dispensing with separators, I shall continue their use, and shall probably make no more cases to be used without them. I can certainly get as much honey by using separators as without them. When they are not used there is constant annoyance from the unfinished sections at the sides, and particularly in the corners of the case, unless the case is left on until all are finished; and no one who expects to produce the best honey can afford to do this. With separators the work of the honey-producer goes on much more smoothly and satisfactorily, and the marketability of the honey is not so dependent on chance.

The wide-frame system is, in my opinion, the best way of using separators, but they should not hold over one tier of sections, and should be so arranged that they can be tiered up to any desired height. Expansibility and contractibility are both valuable features in any hive. A hive should be so made that its capacity may be readily and quickly enlarged or contracted, to suit the extreme requirements of any colony, and so that these changes may be made gradually.

This brings us naturally to a discussion of the Heddon hive, of which more, perhaps, has been claimed in this direction than of any other hive. I have used a number of them during the past season, some of them since early spring. I am thus enabled to form a tolerably correct idea as to the merits of the hive. I had formed a very favorable opinion of it before I had ever seen it, and I must say that, in practice, it nearly fulfilled my highest expectations. There were some drawbacks, how-

ever, which I think ought to be mentioned. You have all heard of its advantages, so I will not dwell on them, but only refer to what I consider its weak points, and its failures to do what has been claimed for it.

The first shock that was given to my good opinion of the hive was when a too ambitious queen found her way upstairs and filled nearly every section in one case with brood. This, of course, can easily be prevented by a queen-excluding honey-board.

A more serious trouble came when dry weather caused the end-bars to shrink so that the set-screws no longer held them tightly enough; and in hives that had been inverted, the frames slipped down until they rested on the bottom-board, almost closing the entrance. Then rains came, and the sides of the hive and the wooden screws swelled so much that I could not turn said screws; and colonies that I particularly wanted to examine might almost as well have been in box hives for all I could do with them. The hives, I may say, were well painted, and the screws had been soaked in linseed oil.

The frames are not nearly so movable as ordinary frames, even when they are new; and I am afraid that, with time and use, propolis will find its way between the frames and the ends of the hive. The heat of summer will melt this propolis, and stick hive and frame so tightly together that, in time, it will be difficult, if not impossible, to remove frames from the hives. This is a very serious objection to the hive. I do not think we can afford to abandon movable-frame hives.

"Why do you want to handle the frames?" I think I hear some one say. Because foul brood is abroad in the land, and an experience with it that has cost me several hundred dollars has taught me that it is next to useless to attempt to get rid of the disease unless it can be detected in its early stages, and that this can not be done except by frequent and thorough examinations of the brood-combs.

I would most willingly adopt the principle of handling hives instead of frames if it were not for foul brood; but with this dread disease threatening me I am afraid to adopt a hive and frame that will make it any more difficult to detect and subdue it.

My next count against the hive is, that it has utterly failed, with me, in one of the strongest points claimed in its favor. We have been told that, by its use, we could secure all the honey in sections, leaving the brood-chamber empty. I found, though, that, as the end of the fall yield approached, the brood-chamber was steadily filled with honey until, at its close, the combs were heavy with honey, to the almost entire exclusion of brood. This was the case with all colonies, blacks as well as Italians, in which the brood-chamber had been closely contracted, although no hives or frames had been reversed during the fall yield. I have about 35 colonies, which were in Heddon hives, or contracted to five Simplicity frames, which I am afraid will not winter well. They are in excellent wintering condition otherwise, but the colonies are much smaller than I should like.

Dayton, Ill., Dec. 23, 1886.

J. A. GREEN.

Friend G., I think you have hit it exactly in what you have to say about "popular crazes." Just now, sliding down hill on a toboggan seems to be the craze in many of our cities; and riding behind a fast young

horse in the daintiest-got-up cutter is not to be compared to sliding down hill and going back on foot, pulling your toboggan after you. As the latter course gives outdoor exercise to some who might not get it otherwise, I guess we had better say amen to it, and not grumble. I have been greatly rejoiced to see Caddie and Connie and cousin Mabel—yes, and Huber too, when the weather is not too cold, exercise their lungs and muscles in sliding down hill, almost from morning till night, in a way they never did before. Dress the children up warmly, and encourage them in rough and tumbles out in the snowdrifts. When our whole nation shall get a craze in that direction, we can thank God for it.—I have felt a good deal as you do, all along, and I am inclined to think Heddon agrees with you, from the fact that he has turned about and adopted wide frames and separators. I think all the difficulties, or nearly all, can be readily remedied. Have the set-screws made of galvanized iron, which may be turned out and dipped in oil occasionally, and I think you can turn them with your fingers. I was surprised when I saw old-fashioned screws on one of friend Heddon's sample hives. The very minute I saw that Heddon recommended a frame almost tight fitting in the body of the hive, I decided at once they would not be very long movable in our locality, on account of propolis. The same arrangement was exhibited at the Northern Ohio State Fair, in Cleveland, years ago, and I afterward saw some hives where the frames had been pushed in when the propolis was soft from the heat of the summer sun. They were about as securely cemented in as you could do it with melted rosin.—In regard to the foul-brood part, friend G., I should say that a bee-keeper has no business having foul brood in his apiary, and therefore need not calculate on it. If the above does hit us, no matter. —Perhaps Heddon, by a different arrangement, will be able to keep the honey out of his brood-chambers.—I think the progeny of certain queens are more disposed to fill up solid all around the brood-nest, than others are.

PRODUCING BEESWAX FOR THE MARKET, INSTEAD OF HONEY.

Can We Not do it Now, Since Honey is so Low?

SOME THOUGHTS AND SUGGESTIONS GROWING OUT OF AND PERTAINING TO THE ABOVE MATTER.

FRIEND ROOT:—This question of wax secretion is really one of the apicultural problems of the day. I have been reading all that I can find upon the subject; I have also been corresponding with some bee-keepers who have been experimenting in something the same line as I have. I have thought about it in the day time, and lain awake nights, and pondered; and it is my firm conviction that we have been losing a big thing in not utilizing the natural wax secretion that is going on more or less all through the working season. I am aware, that when wax is needed for comb-building, the wax secretion is greatly in-

creased; but at the low price at which honey is sold, is it not possible that it would be profitable to *encourage* wax secretion and natural comb-building? To what extent, when, where, how, in what manner, and under what circumstances, it would be advisable to have natural comb built instead of using fdn., will probably take some time to decide; but if we will only start out with this object in view, and *work*, we can find out. In my locality, and with *my* management, I know that the use of fdn. in the brood-nest, when hiving swarms, is unprofitable; but I do not think the matter stops *here*. I think there are still more advantages to be gained by utilizing the *natural* secretion of wax, but just how it is to be done I do not know, and I don't know but I am glad I do not, as there is now before me the *pleasure of finding out*. I have not a particle of doubt that there are times, places, and conditions, when the use of fdn. is *very* profitable; and what we need to learn is, how to use it beneficially.

I sometimes feel impelled to write an article upon this subject, but its magnitude appalls me, as there are so many things to be considered, so many ifs and ands, that I fear I could not do it justice.

Rogersville, Mich.

W. Z. HUTCHINSON.

Our friends will remember that this has been brought up at different times through our past volumes. Friends Hasty and Viallon have given us the most light on the subject, but we are still a good deal in the dark. The above letter from W. Z. Hutchinson was not intended for print, but it comes in so well with several other suggestions that I have taken the liberty of giving it just as he gave it to me, and I think he will not object.

VARIOUS MATTERS.

APIARY NEAR RAILROAD.

A CORRESPONDENT wishes to know (p. 171, 1885) if it will be a damage to an apiary, if located within ten rods of a railroad. As a rule, I should say not; yet if the bees are to be wintered in a cellar or underground cave, the jar from the trains might cause trouble. I have little experience along this line, as I live eight miles from any railroad; but a friend of mine who lived within six rods of the Auburn branch of the N. Y. C. R. R. told me that he believed very much of his loss during winter was owing to the disturbance of his bees caused by this railroad. While there one day he invited me to go into his bee-cave, or special underground repository in which he wintered his bees, about train time, to see what I thought about the matter. The repository was as nice a one as I ever saw, as the sides and bottom were of clean white sand, and kept at a uniform temperature of from 42 to 46°. If I recollect aright it was in December when I was there; and when we went into the cave all was as quiet as I ever knew a bee-cellar. No light was yet made, for he wished me to note the effect of the train on the bees, the same as it would be every time a train passed. Soon we began to feel a slight jar to the ground, and in a moment more the bees began to buzz, or show signs of being disturbed, which increased as the train neared; and as it went by, the trembling of the earth in this dark place was so great that it was any thing but

pleasant to me, and I did not wonder that the bees became so woke up that they came to the entrance of their hives and ran wildly about to see what the trouble was. He told me that this disturbance lasted them from ten to fifteen minutes after the passing of every train; while toward spring they did not get settled down between the passing of the trains. He never was successful in wintering bees in this place, and soon sold out and moved away. Since then I have thought I should prefer some other place for cellar wintering of bees besides one near a railroad.

WORKING QUALITIES OF BEES.

Another correspondent writes (p. 420, 1885) that he thinks that Italian bees work best on basswood and thistle; the blacks on raspberry and buckwheat, and wants my opinion in the matter. After the most close watching of these two varieties of bees during a period of ten years, up to three or four years ago I failed to find a single instance when, or a single plant or tree upon which, the blacks exceeded the Italians in the least as to honey-gathering, while at many times the Italians were actually making a gain while the others consumed their stores. For this reason I discarded the blacks entirely, since which, of course, I have had no opportunity to test them. To be sure I was right, I sent and got queens of the (said to be) *large brown* bees, and of the industrious gray bee; but a thorough trial of both only proved, as I expected, that each was not different from the black bee of our fathers' time. Next I tried the much-praised hybrids, produced by the famed breeder of *Apis Americana*, and found them not a whit ahead of the hybrids which I had had for years; at last, the profit made from my sales of honey from my Italians forced me to part with all other varieties of bees. I know that black bees will store more dark or buckwheat honey than the Italians; but my experience is, that, at the same time this is being done, the Italians are storing more white honey from red clover, whiteweed, and selendine, than the others get from buckwheat. When this white honey is not obtainable, then the Italians store of dark honey an equal amount with the blacks.

CRAMPING OF QUEENS.

When queens are caught by the wings they often double up and appear to have a cramp, the death of a queen having been recorded from this supposed cause (p. 532, 1885). For a long time I supposed this doubling up was caused by a real cramp; but after a little I learned what the trouble was. I caught a queen to clip her wings, when she doubled up as has been described. I thought to let her go as I had always done before when they had thus cramped, but I hesitated, as she was a shy body; and I had had several times of hunting for her before I found her. I soon concluded to clip her, even if she died, rather than hunt for her again; so I lowered my hands very close to the top of the frames and clipped off all the wings as I usually do. She lay on the top-bar of a frame, apparently lifeless, so it gave me a good opportunity to examine her closely, when I soon saw that she had one of her front feet tightly clamped in the opening from which the sting extrudes. In a moment more she began to kick about (as the bees hovered around her, so she saw she was in her own home), when the foot was loosed by the opening parting, and she crawled down among the bees unharmed. Since then I have closely watched scores of queens when thus

doubling up, only to witness the same operation. The queen struggles to get hold of something, so as to liberate herself if possible, and in these struggles curves her abdomen and partly thrusts out her sting. While in this shape one of the front feet catches hold of this apparently secure foothold, upon which the opening is closed from the sensation caused by the foot, holding the foot as in a vise, thus keeping the queen in her doubled-up condition as long as the foot is thus held. I have known queens to remain thus for several minutes, when not returned to the bees. The death reported must have resulted from the foot being stung accidentally while held in this shape. G. M. DOOLITTLE.

Borodino, N. Y., Jan. 1, 1887.

I should think it quite likely that a beecellar within six rods of the track might be objectionable, as you say; however, our bees are, the nearest of them, fifteen rods from the track, and are, of course, located out of doors; and as we have been exceedingly successful in wintering, we can not think a railroad at this distance is any detriment. There is, however, comparatively little travel on our road, and no lightning express trains, as you have on the great thoroughfares. I can imagine these would be more objectionable than the slow-running coal-trains that comprise the greater part of the business on our road.—Your experience with black bees compared with Italians is surprisingly like our own, although we have never tested the brown and gray bee, so much talked of in some localities. I have always been of the opinion, however, that they were common bees, and nothing else.—Your discovery of the cramping of queens is quite new; and until I verify it I can hardly believe it possible that the cases that have come under my observation were all caused in the way you suggest. The queens I have seen seemed absolutely dead, and doubled up exactly as if they had been stung. I have looked them over carefully, to see, if I could, any thing the matter; and when they finally straightened out and walked off, I have been tempted to think they were either frightened out of their little wits, or that they had been "playing possum." Hereafter we will all of us watch and try to verify.

FOUNDATION, VERSUS ITS NON OR LIMITED USE.

WINTERING BEES WITH AN EMPTY HIVE UNDER THE BROOD-NEST.

A COLONY that had been worked for extracted honey was found, in the early part of the winter of 1885, to have taken up winter-quarters in the upper story of the hive; and as they seemed to have plenty of honey I concluded to let them remain there. However, I carefully lifted the upper story and removed the frames from the lower story, that I might see how the bees would winter when so arranged. This was a single-walled hive with glass in the lower part, which gave an opportunity to see how matters went on. This colony came through in good condition, and kept the lead throughout the season. As the honey-season drew on, and the bees evinced a desire to build comb, the lower story was filled with frames having starters only of worker foundation. These frames

were soon filled with nice worker comb, and occupied with brood. The queen being kept busy filling the new combs with eggs, had left the upper story for the storage of honey. So energetically did this colony work under the stimulus of filling the space between the entrance and the upper combs, they were quite as far on at the first extracting as were other colonies that had been given a full set of combs to begin with.

MAKING BEES BUILD COMB BETWEEN THEIR BROOD AND THE ENTRANCE.

By this experiment I concluded that I had made two important discoveries—first, that bees are greatly stimulated and led on to the greatest degree of exertion and activity when induced to go into a "good big contract of comb-building," and that they will begin sooner and work more energetically when building comb to fill the intervening space between their brood-nest and the entrance, than to build comb above the brood-nest. Second, that when building comb beneath their brood, and with a view to extend that brood, they naturally incline to build less drone or store comb. That you may be satisfied with the desirability of this plan for securing nice all-worker combs, you would do well to test it by setting aside, the coming season, some colonies to build combs below, and others to build above their brood-nest. After the trial I think all of the fraternity would read the reports with interest.

HOW TO GET NEARLY ALL WORKER COMB WITHOUT USING FOUNDATION, ETC.

It is my opinion, that a clear gain of a full set of combs will be found, resulting from having the combs built below, the brood-nest, with much less drone-comb and a less disposition to swarm. Of course, in any case less drone comb will be built where the queen is young and prolific. As I must have a full set of combs built for extracting purposes the coming season, and must have them worker comb, I "hedged" in my bees a little last summer and fall by superseding every queen I had over one year old.

WHAT TO DO WITH DRONE COMB WHEN BUILT IN THE BROOD-CHAMBER.

While this question of how to get rid of drone-comb building is before the "house," I want to relate an experience I had summer before last. A large swarm was hived on ten L. frames, no starters used. At the end of one week the frames were pretty well filled down with comb—one-third, or nearly so, drone or store comb. This was all cut out, and, a few days later, on examining I found the frames full and but little drone combs; but what had been built was again removed. Examining a few days later, I found nothing but worker comb in the hive. The drone comb thus obtained was then cut up and waxed into sections, put into a case, and given to the swarm for completion. They were soon finished—the finest lot of 40 one-pound sections I ever saw. Here we have an illustration of how to manage independently of foundation. For any who may have more money than time to invest in the business, I say, buy all the foundation you wish. I only mention this to show that those who will may get on as well without foundation as with it.

JOHN A. BUCHANAN.

Holliday's Cove, W. Va., Dec. 27, 1886.

Friend B., you have struck upon some very important points. First, having a large empty space beneath the brood-combs

for winter, on the plans recommended by Bingham, Doolittle, Boardman, and others; second, having bees build comb between the brood and the entrance. This is an idea that was strongly advocated by Gallup and Adair, as much as 15 years ago. It was given in connection with what they called the "New Idea" hive. Third and last, cutting out drone comb from the brood-nest, and putting in surplus boxes. Mr. W. B. House made a very large crop of comb honey by this means, some years ago. He took both drone and worker comb, however, as fast as the bees built it in the brood-chamber, cut out the pieces, and put it in surplus-boxes. The greatest objection to this course would be the trouble and time.

A BETTER RECORD FOR THE ITALIANS.

AVERAGE YIELD PER COLONY, 281 LBS.; LARGEST YIELD FROM ONE COLONY, 560 LBS.

ON page 977, GLEANINGS, 1886, Mr. E. France, after giving "The Record of Two Students" for the year just closed, concludes as follows: "It seems to me I hear you say, 'They must have been a strain of pure Italians, or some other fancy breed.' Well, they were a pure race of blacks, or brown bees, as you choose to call them—those fellows that some writers say live from hand to mouth—poor despised blacks. They are not so poor a bee after all. Who has got 49 colonies of any other race that has done any better (take a whole apiary through), not pick out 49 of the best?" Well, Mr. France, I have an apiary, not of 49, but of 41 colonies, that did much better than that of your student. They were about as pure Italians, too, as are to be found in this country, several of them containing imported queens. Here is the record: In April, 1883, I took 41 colonies in rotation, without selection as to strength, from my home apiary at Nauvoo, Ill., to a small prairie village five miles east of me. The spring was cold and backward, and the whole season unusually wet. No timber was within three miles. Some fruit and a few black-locusts were the only flowers they had to work on before white clover; and although the colonies were in good average condition, with a great plenty of stores, when removed I was compelled to feed them the last week in May and the first two weeks in June, to prevent starvation, one colony being almost starved before I discovered that they were short. But such a mass of bees! I never saw the like before, nor have I seen it since. The ten large Quinby frames were almost a solid mass of brood, and the hive and surplus box were overflowing with bees. The removal seems to have stimulated them to excessive breeding. The white-clover honey-flow began about the middle of June, and lasted all through July, followed by buckwheat and heart's-ease in August, and ending with Spanish needle, wild artichoke, goldenrod, etc., September 20. The total yield from the 41 colonies was 11,550 lbs. of extracted honey, or an average of 281 lbs. per colony. Greatest yield of any one colony, 560 lbs. I had no swarms—at least, none were seen. I followed the tiering-up plan, always being watchful that each colony had plenty of room for storing honey.

I began the season with 63 surplus boxes, with

frames full of empty comb. I ended the season with 95. I used full sheets of foundation built out in frames. My plan was, as soon as the first box was about half full, to raise it up and put an empty one under it. They continued to work mainly in the upper box; and when the combs were about three-fourths sealed we extracted them and placed the box with the extracted combs below again, next to the brood-chamber. During the first 24 days of July, each 14 colonies gave us one barrel of honey (550 lbs. net) every eight days. This apiary is located on the premises of Mr. William Thornbur, Powelton, Hancock Co., Ill. Mr. Thornbur received one-fifth of the honey as his share, for location, etc.

I have had large yields from some of my other apiaries, but none have ever equaled this one. I have had considerable experience with the Italians, the black (or brown), and the Cyprian bees, and I can truly say that I would not have either of the latter breeds as a gift, for the production of extracted honey, conditioned that I must not Italianize them, although I much prefer the Cyprians to the blacks. I find but one fault with the Cyprians—their unconquerable crossness. Were it not for this I should prefer them to the Italians, as I find the former equal to the latter in every other respect, and much more prolific—one of the best qualities of a profitable race of bees.

EMIL J. BAXTER.

Nauvoo, Ill.

Friend B., we are very much obliged to you for coming forward in defense of the Italians. Other circumstances, however, may have had something to do with your enormous product. Five hundred and sixty pounds from one colony, in one season, is one of the greatest reports ever put on record. The locality must be excellent, and the season was probably very favorable.

DOOLITTLE'S QUEEN-CELL PROTECTOR.

ALSO SOMETHING FROM AWAY OFF IN SOUTH AFRICA.

SOME months ago I wrote you a few items about bees and honey in this vicinity, and my own experience in changing from vicious hybrids to Italians. Before the work was finished, Mr. G. M. Doolittle gave us the description of his wire-cloth cell-protector, and that "Yankee notion" was worth more to me than the cost of your journal, for it settled three colonies that had previously destroyed queens and cells most provokingly. So much time was lost by rearing and introducing queens, when the honey-flow was best, that my increase was only from 13 to 20 colonies, and my honey-crop only twenty-seven gallons; but it seems that, in at least one part of the world, that passes for fabulous success. I reported it to a lady who was once a member of my household, but has been some years a missionary in Cape Colony. You may be interested in an extract from a reply received a few days ago:

"What a nice lot of honey to get from 13 stands! and that reminds me that we are reveling in honey just now. We had fine rains this spring, so the bees found plenty to work on, and the honey is very delicious. The honey-plant is evidently a variety of what we call candy-tuft. It grows in great profusion in the fields, springing up after every slight shower. The honey is whiter than our white-clover,

though I do not think it so fine in flavor. The bees are all native stock, and very vicious, I hear.

"The honey is taken in the good old way, killing two-thirds of the bees by smoking the 'gum,' and so stupefying the others that they hardly recover. I think nearly all to whom I have described our way of handling bees and honey have looked upon it as a *big scam*. I mentioned to some of my teachers last night the amount of honey you had taken, and described the operation of the extractor; but they seemed all to think it just an American yarn. If I had told them you had met a ghost in some of your wanderings they would have believed it. I rather think we shall have something to talk about when we meet."

It will reinforce this lady's reputation for veracity, and may possibly introduce your wares to a new and needy region, if you will send a copy of your catalogue, and a specimen number of GLEANINGS, to Miss T. M. Campbell, Rockland Seminary, Cradock, Cape Colony, British South Africa. I send you stamps enough to pay the postage, if the parcel does not exceed four ounces. DAVID STRANG.

Lincoln, Tenn., Dec. 30, 1886.

My good friend S., when you want us to send price lists or sample copies of GLEANINGS anywhere on the face of the earth, do not, we beg of you, take the trouble to send us stamps. We are just watching for chances to get GLEANINGS away off into the remotest corners of the earth, and it does not make any difference how many stamps it takes to get it there. We are very much pleased to get the good news from your friend, and we take the liberty of sending her GLEANINGS for a year; for, be it known to you and all other friends of the missionary work, that it has for years been our established custom to send GLEANINGS free of charge to any or all missionaries on the face of the earth, so long as they care to read it; so, give us the names of those among your friends who are laboring in missionary fields. We want modern bee culture taught wherever civilization extends. —In regard to the queen-cell protector, some time ago friend Doolittle mailed us a sample, and told us we were at liberty to make and sell as many as we pleased. The price will be 3 cents each; 15 cents for 10, or \$1.00 per 100. If wanted by mail, add 3 cents for 10, or 20 cents per 100 for postage. And in order to start on the right basis, I think we will place \$5.00 to friend Doolittle's credit for what he has done toward giving them to the public.

BEE LEGISLATION, AGAIN.

MRS. HARRISON'S VIEWS.

MR. EDITOR:—I am very sorry to see such a covetous and selfish spirit manifested among bee-keepers as to favor legislation that would deprive any one, so disposed, of the pleasure of keeping bees. They must be looking at the question from their own standpoint, and not from the other side. I well remember the time when I aspired to be a bee-keeper. There were two persons engaged in the business quite extensively, within the city limits, at that time. Both of them kindly assisted me in

every way. One came and divided my two colonies the first season, charging nothing for his services; he lent me books, and gave me sound advice. Honey at that time sold here for 30 and 35 cents per pound. By the time I was firmly established in the business, they were out of it. One of them was a doctor, and he couldn't buy the privilege of doctoring the city, and many frisky practitioners came here and boldly hung out their signs, so he folded his tent like an Arab, and staid away. His bees were scattered around the city, and soon they had emigrated west. The other man had a large lumber business, which increased to such an extent that his bees were neglected, and soon died out. At the present time there is no one person who has as many bees here as we have.

A very pleasant old German, whose beaming face reminds me of friend Muth, comes here occasionally to talk about bees. I asked him lately if he liked bees. His countenance lighted up as he replied, "Oh, yes; I like 'em." This man is too feeble to do heavy farm work; has abundant means, and keeps a few bees for the love of it.

An old lady of this city, past her threescore and ten, has a little apiary of six or eight colonies, and takes a great deal of pleasure in caring for them. An old man past fourscore has 25 or 30 colonies. Now, I can claim priority of location over these old people, but I don't want to take the cup of pleasure from their trembling hands. Brother Root, you would like to purchase the privilege of keeping all the bees in a certain district, and also wouldn't you like to sell all the bee-keepers' supplies in the United States? Thomas H. Newman could have done a big business in Chicago, in selling supplies, if it hadn't been for your mill in Ohio, and the cheap labor obtained there. Was there anybody raising peas, lettuce, beets, and cabbages, in Medina, before you? or selling kites or jack-knives? Would not your business be better if you could do all the selling in Medina or the United States?

I attended a bee-convention at Monmouth, Ill., where one of the members complained bitterly because some others, living four or five miles from town, brought their honey there, and injured his market. He said, "They might take it somewhere else." This same man brought honey to Peoria, and injured my market. MRS. L. HARRISON.
Peoria, Ill.

Mrs. H., I fear you are a little uncharitable in your opening remarks, although I do feel a good deal as you do about the matter as you put it. I think, however, that all of us who know Dr. C. C. Miller know he is not looking at the matter from any selfish standpoint, but, on the contrary, is constantly considering the greatest good to the greatest number. You are mistaken, my friend—I do not want the privilege of selling all the bee-supplies in the United States. A great part of our business is fitting out supply-dealers with machinery and appliances, and we always invite them to look over our works, take dimensions of every thing, and we are glad to have them copy our plans. The saving of freight alone in making hives and section boxes is a very great argument in favor of having supply-dealers located at central points all over our country. We may be thoughtless in some of our remarks and suggestions, my

good friend, but I am sure we are not, many of us, so narrow-minded as the man who thought his neighbors might take *their* honey *somewhere else*.

THE BEE-KEEPERS' UNION.

FRIEND HEDDON'S IDEAS UPON THE SAME.

AFTER reading our highly respected sister Harrison's talk about the Bee-Keepers' Union, and your foot-notes on page 11, I, being the founder of the organization, or, perhaps, I might better say, originator of the same, and am now serving the second year as president of the same, and to-day, as ever, believe with Prof. Cook and many other intelligent and honest bee-keepers, that, if properly supported and managed, it will prove a great success and blessing, it may not displease you by my suggesting a few thoughts contrary to Mrs. Harrison's article. I believe that neither Mrs. Harrison nor yourself have looked at this question from the right standpoint. Ask yourself, first, is bee-keeping, in the nature of things, a legitimate and useful business? Certainly you will say, "Yes." Now, admitting that we may follow it as a business, are we not entitled to the same rights, *vs.* the rights of others, that other lines of legitimate business are entitled to? A railroad cuts through a farm because it can not run under it nor afford to go around it. The odor of horse-stables is allowed to waft out upon the breeze, because it is impracticably expensive to absorb it in the barn, and horse-keeping is a legitimate business. When bees are kept so close to land not owned by the keeper that persons traversing that land are liable to be stung by the bees in defense of their hives, I hold that keeper responsible, because he can prosecute the business successfully without keeping such bees in such manner and in such places that any one need be stung by them in defense of their homes, unless the person stung is trespassing upon the land of the bee-keeper, in which case said person will be held by law and reason to abide by the consequences. I have surveyed the ground many times, and firmly believe that any rights less than those mapped out above will reduce our business to an uncertain "child's play," alike damaging to producers and consumers, and tending to keep us in constant litigation. For 13 years I kept from 16 to 180 colonies within 20 feet of our house, and the same distance from a neighbor's house, in the most thickly settled portion of the town, and in all that time no person, outside of the yard, was stung by one of my bees in defense of their homes. A small boy was stung in the foot by stepping on a bee at work while on white clover. This took place about 40 rods from the apiary. His father, a Jewish clothier, asked me if I ought not to remove the bees from the town. I told him that I might move them when he would move from his barn a stock of rat, mink, and skunk skins which he kept constantly in stock, and which were as constantly wafting their odor into our doors and windows, which were about 12 rods distant. He replied, "Oh! that's all right; I didn't expect you to remove your bees unless you *wanted* to."

You see, the reason why we are overreached in our natural rights is because the people attach no more dignity or importance to honey-producing

now than when the product was produced in fence-corners in "skeps," and was a dripping mixture of bee-bread and honey.

In my first letter upon the subject of our Union, anticipating its possible tendency to create trouble, I guarded against it by particularizing that any member asking aid of the Union must be able to show that no trouble was brewing at the time he became a member, it being the duty of directors to look into this matter in every case when asking the Union for aid. I believe this important feature has been omitted from the by-laws. With this added, and the already healthy arrangement that the Union shall not bear *all* of the expense (and, I should like to add, except where the defendant is poor), but about two-thirds of it, I think Mr. Newman tells us, I see no danger from any of the bad results depicted by Mrs. Harrison. The Union proposes to defend nothing but evident rights; and its board of directors, after carefully examining the law and the facts, will surely be able judges and honest exponents of the merits of the case. I feel that you, friend Root, are not saying as much in favor of our interests as simple justice warrants.

FRIEND MILLER'S LEGISLATION.

I have been opposing Dr. Miller's proposed "legislation for bee-keepers," through the *A. B. J.*, and I want to say that I agree with him fully in nearly every point he makes on page 17 of your last issue, except that I believe it can and will be brought about by the law of "the survival of the fittest," and in no other way. I know that the results of this natural law are sometimes not in harmony with our highest conception of right; but in this case I think they are, and that by it, is the best and only possible way to bring about the ends desired by friend Miller. Any way, he is to be congratulated for the candid, clear, and concise style in which he has vanquished his opponents. To my mind, he never wrote a better article for our journals. We have held convention after convention, and written essay after essay devoted exclusively to "getting on" in the *production* of honey, and now we begin to feel how poverty-stricken we are, regarding our knowledge and works which enable us to add financial success to that of successful producing. I trust that, before next swarming-time—in this latitude—we may hold a convention devoted exclusively to a few very important subjects, closely relating to our success, but not in the line of production. There is much else to look after.

THE HUTCHINSON PAMPHLET.

I have seen yours and friend Bass' call to friend Hutchinson to give us a pamphlet on the subject of the non-use of *Idn.* in brood-chambers, which is as important as it is original. Our hearty thanks and profoundest honors are due to friend H. for his work in this direction, which has been as diligent and successful as novel. Who among us can write a terser, more vigorous, or clearer treatise on this or any other apicultural subject, than friend H.? The addition of other subjects, with its consequent enlargement of the pamphlet, I am sure would be prized by us all. We have none too many books devoted to our chosen pursuit, particularly from such men as W. Z. H., who possesses in so high a degree successful, practical knowledge, and the ability to clearly impart it to others through the medium of the press. I am confident I should profit by it.

Dowagiac, Mich.

JAMES HEDDON.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from Dec. 15.

CHAPTER XXXIII.

The pastures are clothed with flocks; the valleys also are covered over with corn; they shout for joy, they also sing.—PSALM 65: 13.

What a glorious promise, friends, is the little verse above! and how well it comes in with our talks through the previous chapters! But if we would receive these promises we must set about it and do our part, even though it be the middle of January, and in the depth of winter. The question is sometimes asked, what we can do in the winter time. A young friend is just now visiting me, who is greatly taken up with the idea of earning a livelihood for himself, wife, and a baby fifteen months old, on his farm of twelve and a half acres. He has just taken home with him a lot of books and papers to read; but from the talk I have had with him, I am afraid he is reading too much and working too little. I don't believe it is best for a farmer or gardener to spend much time in reading during daylight, in the winter time. As soon as it is light enough to see outdoors, we ought to be hard at work with brain and muscle at something, and do our reading before daylight in the morning or during the long winter evenings; and one of the things to be done is to look after the manure in the winter time; and this brings me to the subject of

PREPARING AND APPLYING MANURE.

In Chapter XIX. we talked about different methods of procuring or making manure at home on the farm, or on our ten-acre farm, if you choose. Let us now consider the matter of getting our manure in shape to apply it to the ground, and of applying it. If your manure is piled up in a heap it will get hot, and burn itself up; and this must, under no circumstances, be allowed. It wants forking over and stirring up; in fact, it wants *breaking* up. In all of our books on gardening and farming, we hear this matter recommended over and over again. In the excellent little work entitled, "Gardening for Young and Old," by Joseph Harris (author of "Walks and Talks on the Farm," etc.), he goes over the matter again and again in his directions for producing almost every crop, and says that the manure must be pounded up and broken up before it is mixed in with the soil. I was especially struck with his directions for raising a nice crop of celery. First, we are to roll and plow and harrow, and roll and plow and harrow again, until the ground is light and

fine. Then you plow furrows, using the double-mold board plow, or, if you have not one, go down and back with a common plow, and then the manure is spread in these furrows. For celery, it needs to be old, thoroughly rotted manure. Then he says, "Spread it evenly, knock it to pieces with a hoe or potato-hook, mixing more or less soil with it, and get it at any rate well *broken to pieces*." We have tried the plan, and it certainly gives good results; but the labor of breaking the manure to pieces is rather expensive. As soon as we commenced at it I began to wonder if there was not some better way. I have suggested, in some former chapter, giving it to the pigs, and inducing them to root it over and break it up.

A few days ago I struck upon another plan for fining manure. We brought in quite a quantity and put it under the benches of the greenhouse, preparatory to filling our boxes for transplanting celery, cabbage-plants, etc. The manure was good, but it was in lumps and chunks; and as it was rather damp it was quite a task to break it up with rakes and sieves. Our brood of chickens that were raised to catch green flies in the greenhouse got too big for the purpose; and as they showed great dexterity in scratching whenever they were permitted to get on the lettuce-beds, I took the hint and confined them with wire-cloth poultry-netting under the benches. A little wheat scattered among it did the business. A hen and chickens can break up dirt or manure, probably better than any machine ever invented. As they oftentimes "work for nothing and board themselves," why not turn their wonderful talents in that direction into some useful channel? Our poultry-journals have had a good deal to say, and keep talking constantly to us, about providing employment for the fowls in winter. Gather forest-leaves, or provide cut straw; then scatter your grain among this and let them scratch it out. Now, it would cost me money to gather forest-leaves at this time of the year, and it would cost me money, also, to provide cut straw; but our manure-heap under the shed (pictured in Chapter XXXI.) is right handy to the poultry. They had been digging it over some, and I took down a rake, provided myself with corn and wheat-screenings, and

very soon had the grain scattered through the coarse manure. Why, it just made a "picnic" among the Brahmas that had been standing idle, first on one foot and then on the other; and this morning I heard a chorus of cackles that pretty surely indicates that eggs are not far in the future, even if it is only the first week in January. Now, friends, instead of being annoyed by the scratching of the poultry, can we not turn this scratching into a useful channel, so that the more scratching they do the more we feel happy? Terry tried to arrange his work, you remember, so that he felt happy when it rained on his potatoes; but if it did not rain, he felt happy because it gave him a chance to get in his clover. There may be other domestic animals that can be employed to break up, fine, turn over, and prevent from heating, our accumulations of manure-heaps, but I have not discovered them. While on the subject, I might add, that, if the manure from the poultry-house is placed on the manure-heap, and worked over in the way I have suggested, I think it will be the easiest method of applying it to our ground, and I think it will also do the most good. Now, although you may keep a very large flock of fowls, it is hardly probable that they can work *all* your manure up that is to be used on your grounds. Is there any thing in the way of machinery to do this work? In my former chapters I have several times alluded to the manure-spreader, but I have only now got ready to consider the machine fully. We give a picture of the latest improvements in this line, so far as I know, below.

up the manure by revolving so rapidly that it breaks and tears manure of any description, as the machine moves along. Instead of having a man to throw it off in forksful, without breaking it up, the machine throws it off, scatters it more evenly than could possibly be done by hand, and at the same time tears it to pieces and breaks it up fine, in a way that no sort of handwork could possibly do. The great objection to these machines has been their cost, which used to be from \$125 to \$150. They are now, however, reduced to about an even hundred, and that for the very best machines made, so far as I know. Notwithstanding the large price, the manufacturers who produce the machine shown above had, in 1884, sold nearly 1000 machines in different parts of the United States. They furnish a list of parties using them, so those who want to buy can ordinarily see the machines at work, without going a very great distance from home. Of course, it would not pay one to invest in such a machine unless he has a good many loads of manure to spread. Let us figure it this way: The interest on the money would ordinarily be \$6.00 a year. If the machine is carefully housed and properly used, it would probably last fifteen or twenty years, so you might say that the wear and tear of the machine would be perhaps as much more as the interest; therefore, unless the machine can be made to be worth ten or fifteen dollars a year, it would hardly pay to buy one. In view, however, of the fact that it puts all the manure on the ground in so much better shape than can be done without it, as well as in saving

MANURE-SPREADER AT WORK, BROADCASTING.

You will notice the cylinder, with spikes in its circumference, something like the cylinder of a thrashing-machine. This tears

of time, it might be best to make the purchase, even if the time saved does not amount to more than ten or twelve dollars

a year. I believe it takes about 20 or 30 minutes for a good stout man to scatter a load of manure. A spreader will do it as quick as a team can go from one end of the lot to the other. In fact, we have our heaps of manure at each end of the lot, so that we throw a load on at one end, drive across, load up again, go back, and so on. Our best authorities on market-gardening recommend from fifty to one hundred loads of manure per acre, every season; suppose, however, we say 25. A man with 10 acres of land to be manured each year would have 250 loads to spread. If the labor saved by the use of the spreader amounts to only 10 cts. a load, we should have \$25.00, and I think it would pay well, under the above circumstances, to purchase a spreader. In view, however, of the *better results* to be obtained, we might say it would pay with only

joining farmers had from 12 to 15. There is much manure hauled out and put in piles that is a waste.

C. H. McCULLOUGH.

Troy, Ohio, Nov. 23, 1886.

The point made in the above is, I think, an excellent one. I know that about all the leading authorities on agriculture are now recommending that manure be not put on the ground until either just before the crop is put in, or even *after* the seed is put in, as above; and some advise that half of the manure be put on at the time the crop is put in the ground, and the other half to be put between the rows when the crop is partly grown. Peter Henderson emphatically advises, in his recent writings, that the manure be finely spread on the top of the ground, after the ground is all properly fitted, instead of being plowed under.

The best machine for working the manure into the ground after it is spread by the ma-

THE ACME CULTIVATOR.

five acres to be manured every season. In regard to this latter point, I submit a letter from one of our Ohio men, that the manufacturers of the manure-spreader sent me some time ago:

Messrs. Kemp & Burper Mfg. Co., Syracuse, N. Y.:—

I thought I would send you a line in regard to my manure-spreader. I have been using it about three years, hauling out from 200 to 300 loads per year, and have had no occasion for repairs of our own breaking. I have been hauling pure cow-dung to-day that we could not have spread off a wagon with forks. I would not take \$200 for mine and be without it. I can unload quicker than four men can load it. When I loan it out I charge \$1.00 per day for it. A word in regard to its use on my wheat ground. I sow my wheat, then go over it with the spreader, putting on about 15 loads to the acre. This year I had 27 bushels to the acre, while the ad-

nure-spreader, is the Acme harrow, described and illustrated in Chapter XXVI. Where the manure is spread over the ground after the crop is partly up, of course the full-sized Acme can not be used; but the manufacturers have lately brought out what they call the Acme cultivator, figured above.

This works the manure in beautifully, and is the best cultivator I have got hold of for breaking the crust on the ground, working it up fine, and leaving the ground level after it is passed over. We have used it during the past season, with the greatest satisfaction, between the rows of celery, until the plants were large enough to need a little earthing-up. A neighbor has also used it for cultivating corn; and although

he has a two-horse cultivator, he used this, saying it did the best work in the cornfield of any thing they ever had a horse hitched to.

I have said so much in favor of the manure-spreader, I will now mention its disadvantages, so far as I can, after having used it part of one season and the whole of another. First, it needs a good stout team to work it, especially if you have manure in solid hard chunks, or cow-manure, as mentioned above; and even with a good stout team it is not advisable to put on as heavy a load as the same team would ordinarily draw on a wagon. There may be some difference of opinion in regard to this matter, but we have tested it pretty thoroughly. We buy our manure all over the town, and buy it at so much a load; therefore it is desirable to get about as much as the horses can draw conveniently. Of course, we have a good team; but if we put on as much as the horses can draw, it is a pretty severe strain on the machinery. We at first tried tramping the manure down, but this will not answer, for two reasons: It gets too much weight on the machinery when the manure is heavy, and the strain is much more severe on the cylinder that picks it up. On a recent visit through adjoining counties I noticed that those using manure-spreaders drew their manure to the fields in wagons, and threw it down in heaps at each end of the field, as I have described. The machine was then set so as to spread a load in going once across.* This necessitates, of course, pitching the manure on to the ground, and then from the ground on to the spreader. I remonstrated at this, calling it a waste of time; but they told me I would find it again in the end, and our experience has proved them to be correct. To have the manure spread nicely and rapidly, it must not be packed in the spreader at all. Let it lie just as lightly as you can throw it in; and although you can work it when piled above the sides of the box, especially when the manure is very light, as a rule the stopping necessitated by so doing to run the box forward and pitch the manure back on to the empty space takes more time than to throw in just what will spread without stopping. Better follow the printed directions the manufacturers send out with the machines. We have had some repairs to pay for in consequence of trying methods of our own. Our friend in the letter above speaks of loaning

the machine to neighbors. It depends upon who the neighbors are. On one occasion a neighbor set his hired man at work with it, and it was run without oil until two of the wheels were cut so as to be worthless. It seems to me the better way would be to have the man, who is accustomed to work with the machine, go with it, for it is necessarily, in some respects, a rather complicated piece of machinery; and, as friend Terry says, it must be housed or it will prove to be an expensive piece of machinery.

SPREADING ASHES, LIME, PLASTER, SAWDUST, ETC., WITH A MANURE-SPREADER.

I believe it is generally agreed, that ashes are a benefit on almost any soil; but lime and plaster may be needed only in certain localities; but as they are used quite extensively in some places, I presume there is no question as to their utility. When I was a boy, riding a horse for cultivating corn, even to my boyish eyes there was a plain difference in the corn that had received a table-spoonful of plaster scattered on the hill, from that which had received none, and it was put on certain rows and not on others, so there could be no mistake about it. This was on sandy soil, however. I have never seen this tried on clay land. In regard to sawdust, there seems to be a great difference of opinion. I presume, however, the *kind* of sawdust has very much to do with it. Sawdust from hard wood, such as is found in many of our country sawmills, is, without doubt, valuable when it is old and well rotted. We frequently get such sawdust in our vicinity as has been so long in the ice-house that it needs replacing. Two years ago we were offered a lot of this kind for hauling it away. We put it around some of our strawberries for mulching. The plants thus mulched made a much better growth, and made larger fruit in great abundance; but as the sawdust was put around the plants by hand, the labor of putting it on cost more than the benefit accruing was worth—unless, indeed, the benefit shall continue for a number of years, which is not unlikely. When applied, the vines were covered with green fruit, and it was therefore necessary to hold up the fruit-stems and put the sawdust up under the foliage. The labor cost me about \$2.00 for covering only a few rods. Now, had this been done with a manure-spreader at the proper season, the whole would not have cost over 50 cents. It is well to look out about going into any speculation that is going to take such an amount of expensive handwork as the above. I did it, principally

*Where two teams are accessible, one may draw the manure to the lot, and pitch it directly from the wagon to the spreader, some extra piles being placed in advance on the ground, to keep the spreader going until the team gets back.

to satisfy myself as to the benefit of old rotten sawdust. On our stiff clay soils, this old sawdust seems to have a very beneficial effect; but I presume swamp muck would answer just as well, and may be better, for both of them are decayed vegetable matter. I have been under the impression that sawdust is particularly beneficial to raspberries and strawberries. Who has not noticed the exceedingly fine growth and fine fruit of the raspberry and strawberry, when growing near decayed stumps, or old rotten logs? Now, with the manure-spreader we can put on just as big a load of sawdust as we have a mind to, and the machine will spread it over the ground most beautifully; throwing it down between the foliage, and breaking up fine every lump there may be in it.* If your strawberries are put in rows the right distance apart, the manure-spreader can be run through them at almost any season of the year, to spread sawdust, muck, ashes, or even stable-manure; and if stable-manure can be thus spread among the plants, just before a good heavy shower, it seems to do more good than any other way in which I have applied it. The machine can be set so as to spread at three different rates of speed; and where you wish to put only a very thin sprinkling of lime, ashes, or plaster, over your ground, the quantity you have may be spread over a still larger area by having the box of the manure-spreader only half full or less. Let any one take a load of ashes, and try to spread it evenly by hand over a piece of ground, and then see the manure-spreader do it, and he will be satisfied of the merits of the machine.

Perhaps some of the friends may think it a little strange that I should say so much in praise of so expensive a piece of machinery for the simple purpose of spreading manure, and nothing else, in a book that is written purposely to tell those out of employment what to do. To which I reply, that people who own property are very often in want of something to do, as well as those who have nothing in this world. If I can suggest to a farmer or gardener a way of finding work on his own premises, instead of besieging our mills and factories for employment, I think I am doing him a service; and in no way that I know of can we succeed in mak-

ing a man so permanently happy and satisfied, as by encouraging or inducing him to find employment on his own premises. The enjoyment resulting from working the ground is in having good crops; and without plenty of good manure, properly applied to the soil, there can be no satisfactory returns. Some years ago the matter of getting honey from the gooseberry and currant was discussed in one of our bee-journals. One brother mentioned that the only time he ever saw bees gather honey and build comb in real earnest from gooseberry and currant blossoms was when he gave his whole currant-patch a tremendous manuring. His wife had been teasing for a lot of nice currants, and, to please her, he just covered the whole ground with manure. The bushes, of course, made a correspondingly luxuriant growth, and the year after they not only had currants by the bushel, but they had finer currants than any one ever saw or heard of before around there. Now, it is so with almost all kinds of fruit. It is not, however, the amount of manure which is put on, but it is the way it is applied. If you use your eyes carefully you can see how it is that plants take the manure and work it into luxuriant growth. The manure needs to be applied in such a way that, after a warm summer shower, the dark-colored liquid that comes from the manure shall go directly to the roots of the plants. Now, many of the roots are much nearer the surface of the ground than most people imagine. The roots of the strawberry and celery are close to the surface of the ground. Why, we know, without telling, that this dark-colored manure-water, seen on the surface of the ground around the plants after a heavy shower, will surely bring the rich dark-green leaves, pushing up and bursting forth so rapidly that they almost seem to move. The finest growth of celery I ever saw in my life was on a little piece of ground close to a line fence between myself and a neighbor. His manure was on higher ground than the celery plants, and after a heavy rain the water ran down from the manure-heap all over my plants in such a way as to leave inky puddles for several rods. The celery was the last put out of the season, and it consisted of the remnants of a bed which I had not intended to make any use of. Before I knew it these plants had shot up so that they fell over and lay sprawling on the surface of the ground. We went at it and earthed them up in the most approved manner; but in a week they were sprawling around again. We banked

* If the sawdust is spread in the spring or fall, the strawberries will shoot right up through it, and it wouldn't do any hurt if the foliage and crowns were covered slightly, say half an inch or less; if, however, it is put on after growth has started in the spring, or while the plants are growing, the sawdust should be shaken off by gathering up the leaves and lifting them up to the light.

them as high as we could, and then set boards on top of the ridge, and banked them a foot higher. The celery was still growing when frost came, and the quality is so crisp that every bit of the plants is edible—there is no hard stalk about it. They are so crisp that, unless great care is exercised in handling it, it snaps up like pipe-stems. Now, then, to raise almost any kind of a plant, we want the ground underdrained and then worked up mellow and fine. Now work into the surface of this mellow ground a good lot of fine manure, put on just as the manure-spreader does it; then sow your seeds or set out your plants, and put on another thin covering of manure. If there should be a dry time after this last coat of manure is spread over the surface, there may be some of the manure lost by drying up—at least, some farmers think there is, but I do not feel sure of it. When a shower does come so as to wet the surface of the ground, there is manure enough to make the rain water look dark-colored; and this dark-colored water around the seeds and roots of the plants is what brings the crop. Manure plowed under may make a crop, it is true; but my opinion is, that it takes more, and does not act so quickly, as the plan given. A very little manure will color or darken a very large quantity of rain water. While I was attending the Ohio State Fair, one of my men discovered that a manure-heap was heating. He therefore turned the hose from the stables, near by, on the heap, and left it while he did something else. He let the water run rather longer than he intended, I presume. On my arrival home, the first thing I did was to take a look over the grounds. Imagine my surprise to see the water of the creek darkened as if somebody had been pouring coffee into it. I followed the coffee-colored streak at one side of the stream until it came to the outlet of an underdrain. Sure enough, the dark-colored liquid was slowly trickling from the tiles. I followed the drain until I came to the manure-heap, and, digging down into it, I saw that it was wet. I hunted up my man, but he insisted that

there could not have been water enough put on the heap to make any great waste. Now, very likely one load of *good* manure would color a stream of water for a mile; but my experience indicates that, whenever the water is colored so as to be perceptible to the eye, it will make plants grow. The question has often been asked, if the system of underdraining commonly in vogue does not in this way sometimes carry off the strength of the manure. I have watched the matter closely; and although I have seen it do it to some extent, after very heavy rains, I believe the loss is very small where the underdraining and spreading of the manure was done as it should be. If the underdrains are down fully three feet in depth, and your ground is worked up fine and soft before the manure is spread on the surface, this fine soft ground filters every thing valuable from the water before it reaches the underdrains. If, however, your manure is plowed under, so as to lie on the bottom of a hard furrow, and your underdrains are filled with hard lumps, of course the first rain carries the strength of the manure off to the roadside or to the outlet of your underdrain. This should be carefully guarded against; and the Acme harrow, such as I have described, and manure-spreader, are the things to do it.

In regard to the expense of these machines, you can test the matter for yourself. Make a bed in the garden, with a spading-fork and rake. Put on the manure with the wheelbarrow, and rake it in by hand. Measure the area you have worked, and see how much it costs per acre to do it. Now fit an acre with modern tools, and figure again the cost of team, interest on money invested in tools, and see which is the cheapest. I do not mean to discourage working with fork and rake; for small patches for early vegetables must oftentimes be got ready in this way; and the extra price received for the crop will pay for so doing. But just as soon as circumstances will permit, we should let horse-power take the place of hand-power—not only in getting the ground ready, but in spreading and working the manure.

CHAPTER XXXIV.

Whosoever shall exalt himself shall be abased; and he that shall humble himself shall be exalted.—
MATT. 23: 12.

Thus far in our book our talk has been principally about "What to Do," and but little has been said about the latter part of the title—"How to be Happy," etc. I think our happiness, to a great extent, depends

upon our surroundings. We are also happy when our plans succeed. Most of us are planning and working with busy brain. Even during the night time we lay out our work and contrive ways and means to ac-

comply with certain results. If, when we come to put this in practice, and the result equals or exceeds our expectations, we, as a rule, feel happy over it. I have seen a great many young people made unhappy by putting their expectations too high, and I have been through a good deal of this experience myself. I have always been in the habit of working more or less with tools. But one sad thing about my work, and one source of great unhappiness, has been that I planned too much in rainbow colors. Especially was this the case when I was a boy. I would decide to build some implement or some piece of furniture; and as I was short of means I concluded to do the work myself. When the article was finished it almost invariably took more time and money than I had figured on, and, with few exceptions, it did not work as well, nor look as well, as I had pictured it in my imagination. A good many times it had to be abandoned, and it was often laid aside, or allowed to stay where I last used it, an eyesore and a cause of unhappiness every time my eye rested upon it. I remember one day, when father and I were planting corn. I had seen a hand corn-planter, and I told him I thought I could make one. He objected, on the ground that my machines didn't work, and that I would be wasting nails and lumber. I told him, however, that if it did not work I would pay for the lumber, and I would draw the nails all out and put them back in their places. Under these conditions he consented. It did not work, and, with a sad heart, I pulled it to pieces, put the nails away, and cleared every thing up out of sight, as if no corn-planter had ever been made. It was a useful lesson to me. The next time I wanted to indulge my inventive faculties I remembered the corn-planter, and was saved some unhappiness by not going into it. About this time I began to discover I was not a good mechanic—at least, that I was not a good carpenter and joiner. The principal reason was, I never took time to do my work nicely, and this oftentimes occasioned failure. Besides, where a machine succeeded it looked so unsightly that I was ashamed to have it seen. I concluded to have my line of work, and work at it; and when I wanted to have carpenter work or blacksmith work done, get a carpenter or blacksmith to do it. I find the same disposition among many of the young friends who are at work here. A young man thought he could make a corn-marker; his employer told him he could not—he had not had the experience. But the boy

had quite an opinion of his mechanical abilities, and so he went to work without permission. It took him three times as long as it would have taken an experienced man, and it kept giving out in one place and then another until it was quite a source of unhappiness all round. The young man who has charge of our greenhouse has become quite skillful in making seeds and plants grow, but he makes terribly poor work when he attempts to put up shelves or benches. I have had hard work to convince him that he is not a good carpenter; and, furthermore, that it would not pay him to learn to do good carpenter work. I told him I was quite satisfied that he could, by serving an apprenticeship, learn to do nice carpenter work, and do it quickly; but as he had chosen to work with seeds and plants, he could earn much more money by sticking to his business than to try to put up shelves and benches. One of his fellow-workmen, who receives the same pay he does, would do the work nicely and quickly, without any showing or educating. Now, although I most heartily advise having a shop and some carpenter tools on every farm, or around every home, I think it quite important to beware of undertaking work you can not do profitably. If a farmer or gardener has spare time during the winter, or during evenings, he may practice using carpenter tools; but when he has something else to do in his own line of work, for which he can earn wages enough to pay a carpenter or blacksmith, I would say, "By all means do it."

I have now given you some sources of unhappiness, the moral to which would be this: If you want to be happy, and enjoy your work, be careful about putting your expectations too high. If you have attempted a good many things, and failed, let these failures teach you a lesson; and the lesson is, that you do not *overrate* your own *abilities*. I have now in mind a very good person, whose life has almost been made a failure because he constantly insists that he is capable of directing others how to do work; but the truth is, he has never first proved his ability, by making a success in small things. The fact that his life has been a series of failures does not seem to have taught him humility at all. In contrast with his disposition I remember a young man who asked me for work; and when the subject of wages came up he said, "Mr. Root, give me exactly what *you* think I am worth, and I shall be happy and satisfied." He is now receiving a thousand dollars a year. I do not mean to say

that this plan will answer under all circumstances; but in this case it has always kept a very pleasant feeling between himself and myself. Instead of complaining that he does not get what he deserves, or that he does not get credit for all he has done, he is constantly striving to see how good a record, or showing, he can make each year, and that record, or showing, pleads for him. The action takes the place of words. He has never said, "Mr. Root, don't you think I am earning a little more than you pay me?" But the *results* of his efforts with brain and muscle often say to me, "Mr. Root, that man is doing splendidly, and it begins to look as if he is really worth more money than he is receiving."

Right in line with this talk is one of the greatest sources of happiness. You may build air-castles in your own mind, my young friends, but do not tell them out loud, and do not get your expectations up too high. The young relative of whom I spoke in a former chapter is going to try poultry on his 12½ acres. He said he believed he could make every hen earn him a *dollar* a year. I think he is putting his expectations too high. I should much rather have him give an accurate statement of what he *has* done with hens, than to hear him tell what he is *going* to do. He has an excellent locality for fowls, and he can easily make a nice room for them in the side of a gravelly hill adjoining his barn and stables. One of the poultry-journals states that it will cost 10 cents a month to keep a hen, where you are so situated as to be obliged to buy every thing. If you raise it, it will cost pretty nearly as much; that is, what you raise ought to be worth the market price. If he keeps only about 50 fowls on an average, they will probably get their own living on his 12½ acres, six months in the year. This will reduce the expense to 60 cts. If they lay 100 eggs apiece in a year, I think they will do pretty well; and I think he will do pretty well if he makes his hens pay a clear profit of 50 cts. each. If he makes this his estimate, and then does *still better*, he will enjoy keeping poultry. If, however, he fixes his figures at a dollar each, clear profit, and gets only 50 cts., he may feel somewhat like grumbling; and if his poultry should cost him more cash right out than he gets back in a year, there can't be very much happiness of any kind about it.

Now, boys, in view of this, don't set your

figures too high. Make up your mind to put in an earnest, hard day's work every day in the year, with brain and muscle, and then decide to thank God, the great Giver of all good, for whatever he gives you. In these remarks I would not think of discouraging a young man from trying his hand with tools—especially, *simple* tools belonging to almost any trade or industry; but I would discourage the habit of having a great lot of tools about him that he can not use enough to pay the interest on the money; and especially would I dissuade him from thinking he is smart enough to do any thing that *any* mechanic can do, with his years of experience and skill. One of the rising sins of Young America is a disposition to think he is smart enough to earn good wages at almost any calling, without learning a trade. Almost every day, nice-looking young men are coming to me, begging for a place. Sometimes I ask them if they have any trade, or what they have been accustomed to work at. The reply comes, almost every time, "I have not worked at any thing but odd jobs; but I guess I can do almost any thing you want done." We are just now in want of a printer; but I have not asked any of these young men if they could set type. I am quite sure they would think they could, and no doubt they would go to work without a bit of trouble, provided I would pay them 10 or 12 cts. an hour while they are learning how, and they would think they ought to have this, even if it took an expensive and skilled man to teach them, and even though they were a good deal more trouble than they were worth.

Do you see where we are tending, friends? Thousands upon thousands are wanting something to do, and yet, when wanted they do not know how to do it. Do you ask what I advise right here? I advise you to do exactly as the boy did who is now earning a thousand dollars a year; yes, even though you do not earn enough to pay your board, for you had better work for nothing and board yourself than to remain idle. If you can't get a chance to do even that, get some type, and go to work at home by yourself. Take good, well-printed books for your guide; and when you can do some nice printing, take a sample of it to some printing-office, and tell them you have got far enough to do work like your specimen. I think you will soon find a place where you can get *every cent you are worth*.

To be continued Feb. 15, 1887.

SPREADING BROOD IN THE SPRING.

THE DANGERS ARISING FROM THE PRACTICE.

THE discussion at the Indianapolis Convention that interested me most was that over the above subject. I ached to ventilate some of my own views on the subject, but could not get the floor—because I am so small in stature, I suppose. If the editor of GLEANINGS will allow me the floor in this great informal convention of bee-keepers, my thoughts may come in good play, as spring will not be very long in approaching.

I take the ground, that inserting a frame of honey in the center of the brood-nest, to stimulate brood-raising in early spring, is generally unnecessary, and often injurious. It is a reasonable theory, which I think I have proven by observation, that the instinct of a good queen is to fill about six L. frames as rapidly as conditions will permit. If she is a poor one, no amount of coaxing will make the matter much better. Now, what are right conditions? They are, a sufficient quantity of proper stores, either in the hive or coming in, favorable weather, and healthy bees enough to take care of the "babies." The place to secure good food and healthy bees is not shade. My experience says that there is scarcely any thing worse for bees in spring than that. A flat, damp site may be perhaps as bad as a shady one; but it is no worse. Shade is an excellent harbor for dampness, and for wet, moldy hives and diluted honey. The latter will breed more or less disease.

Healthfulness is a more important factor than is generally supposed. I have known a form of dysentery, as it seemed, to cling to a colony in a shade, or a flat, until along in April, and they would dwindle in spite of all the brood and bees I might give them. If there is any case when one may safely and advantageously spread the brood of a colony with from only two to four frames containing brood in each in early spring, it is when the hive sits right out in the sun. Unhealthy conditions make bees puny, and exposure and hard work wear them out. Why should they not? Right here, it appeared to me that those wise heads at Indianapolis foraged all around a point of great importance. Several objected to spreading brood, because it would so often become chilled in the operation. Have they never thought about the poor bees? While the system may, with care, be sometimes practiced to advantage, I have reached the conclusion that spreading brood is unprofitable, not so much that it is death to the brood, as because it is death to the bees.

Prof. Cook names, as one advantage of sugar-feeding in early spring, that it largely obviates the necessity of bees going out after water in unfavorable weather. Within the hive, the additional labor imposed upon the workers, scanty in numbers or puny in health, by the process of forcing (consuming and feeding, and in protecting such quantities of brood), is wearing upon them. When they must go out on those cold, cloudy days to get water from those chilling, mucky pools, many of them become numbed and never return. I have known a colony to lose in numbers very perceptibly in one week's time, under this kind of treatment. Our wet, backward seasons are one of the most unfavorable conditions, and forcing rather augments than overcomes the evil. When weather and other essentials

favor it, the instincts of both bees and queen are to multiply.

But I am inclined to think that, by the time about six frames become well filled with brood, and well covered with bees, that the case becomes altered. Beyond this number the queen is not nearly so apt to reach out and fill up the outside frames. Then bees are hatching rapidly, and the weather has generally become warmer; while one can at the same time insert a frame of honey and have the queen fill it with eggs, without making the same draft upon the energies of the bees, as if there were only enough to cover four frames well instead of six.

Whatever may be the wisdom and value of the above conclusions, I am certain that, if we would practice stimulation in early spring, we must proceed very cautiously, and be sure that conditions are favorable.

—GEO. F. ROBBINS, '93 '61.

Mechanicsburg, Ill., Dec. 22, 1886.

RED RASPBERRIES AND BLACK BEES.

MILKWEED HONEY.

ALTHOUGH white clover is indigenous to our locality, it is quite a rare thing for bees to work very hard on it. Indeed, in some seasons when it blooms profusely they will not work on it at all. The reason for this disregard of clover is the abundance of a much better honey-producing plant—the wild red raspberry.

This section has been timbered largely with hemlock which has been cut off, leaving a mass of brush ready to catch fire. Almost invariably after these tracts burn over, the red raspberry springs up. There are hundreds of acres of this plant within range of our bees. Its period of bloom is identical with that of white clover. By its color and consistency, its honey can not be distinguished from the white-clover honey, but it is far superior to it in richness and delicacy of flavor.

Basswood is also quite abundant here, and we occasionally obtain large crops of honey from it. Unless, however, the weather is just right it yields little or no honey with us. During the last two seasons we have not obtained an ounce of surplus honey from it. Both these years the weather has been cold and rainy while it was in bloom.

Milkweed furnishes quite a large quantity of honey, blooming just after raspberries, and just before basswood. This year my 62 colonies gathered a little over a ton of its beautiful, thick, amber honey, in six or seven days. This makes an average of about five pounds per day per colony. I have been greatly surprised at the complaints of the little appendages which entangle the bees' feet. I have watched closely, and have never seen a bee entangled.

A REPORT FROM BLACK BEES.

I started last spring with 61 colonies, three of which were very weak, and made no surplus honey, but built up into strong swarms by the time the honey-season was over. This report is, therefore, actually from 58 colonies. I received 6112 lbs. of honey, of which 1213 is comb, the rest extracted. About 3500 lbs. of this is from raspberry, with perhaps a little white clover mixed with it, about 2000 lbs. from milkweed, and the rest, 500 or 600 lbs., from buckwheat, goldenrod, etc. I have 87 colonies packed away in chaff hives, all in good condition at the present writing.

My bees are all blacks. I have never had any ex-

perience with Italians, and can not, therefore, intelligently compare the two races. I have never had any trouble with moths, but have to watch the bees very carefully to guard against robbing. A neighbor, about six miles distant, who has two apiaries containing over a hundred colonies, nearly all Italians, told me he has obtained a little over 3000 lbs. of extracted honey. 6—WILLIS EARLY, 61—87.

Sherman, Pa., Jan. 4, 1887.

MAKING HONEY VINEGAR

SOME VERY IMPORTANT SUGGESTIONS IN REGARD TO THE MATTER.

WE make several barrels of vinegar every year, and sell it to the folks in town, at 25 cts. per gallon, and have had no trouble so far to sell all we had. The demand is increasing every year, selling to some of our merchants' families who are selling vinegar at their stores, which they buy of the trade in Chicago. I asked one merchant's wife why she bought my vinegar. "Oh!" she said, "the store vinegar eats up my pickles." It takes two pounds of honey to make a gallon of vinegar, and two years' time to make. We make the most of ours out of refuse honey, or honey that we can not use for any other purpose, and would otherwise be lost or wasted. We retail a large quantity of honey; and when the honey is candied there will be considerable left sticking to the sides of the barrels. We always wash out all the barrels we expect to use again. The first washing that takes off the honey, we put in the vinegar. It is clean; it is nothing but honey and water. Then, again, when we are extracting honey we have a box with a wire-cloth bottom which we set over a barrel that has the upper head out. Into this box we put what cappings we have to drain out the honey. In 24 hours we empty those cappings into a barrel that has some water in it, to soak out what honey remains, straining them once or twice a day. The barrel will hold what cappings we get in a week. About once a week we strain out the water and put it in the vinegar and melt the cappings into wax, so there is nothing lost. I don't like to see any thing thrown away that we can use. Again, there is always more or less honey that can be made into good vinegar that is not just fit to sell for nice honey. In that way it is saved.

To know when the water is sweet enough for vinegar, put in a good fresh egg, and make the water sweet enough to float the egg so there will be a patch of the shell out of the water about as big as a silver 10-cent piece; then it is about right. We keep ours standing in barrels, with one head out, to give it air; for air it must have to make vinegar. Tie a square yard of cheese-cloth over the top of the barrel, to keep out dirt and flies, and other insects. Keep under cover out of the rain, in a warm dry place. We keep ours standing in one corner of our shop through the summer, and put it down in the cellar through the winter, and take it up again when spring comes. When we are changing either in the fall or spring, we find some that is fit for sale. We take it into our dwelling-house cellar and put it into our retailing barrels, which we keep there for that purpose. I have been thinking of late whether it would not be a good plan to make up all our cheap honey into

vinegar; but I don't know how much it could be sold for at wholesale. I must look this matter up. It may be that we can do something in this direction to relieve the market of our low-priced honey. Honey is getting to be so plentiful and cheap that we must turn it into every channel that will take it.

Platteville, Wis.

E. FRANCE.

Friend F., your suggestions are exactly what we have wanted for a long time, and we are especially glad to have you give us the full details of the matter. The question has been asked over and over again. "How much honey is needed for a certain quantity of water?" Now, as honey varies so greatly in density, it has been very difficult to give any positive formula; but your plan of trying it with an egg fills the bill exactly; also in regard to the temperature of the place it is kept, and the amount of air to give it. I think every one of our readers can go to work and make vinegar, with such directions. Good cider vinegar is worth here from 10 to 12 cts. per gallon by the barrel.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

HONEY EXHIBITS AT FAIRS.

GLEANINGS of Dec. 1st at hand, containing cut of my exhibit at our county fair. I feel greatly indebted to you, and thank you for your very able notice. Your remarks echo my sentiments precisely, in regard to the advancement of bee culture, and I know of no better place that we can come before the people and show and explain the rapid strides that this important branch of agriculture has taken, than at our respective county fairs. At present our fair officials do not notice this branch as they should, but it rests with us to make them as attractive as we possibly can, and *attractions* please the managers, and then no doubt we shall be classed and made permanent as attractions now are. "To educate the people" should be our aim at the present, and we can ill afford to hide our candle under a bushel in this advancing age. E. R. NEWCOMB.

Pleasant Valley, N. Y., Dec. 6, 1886.

SEALING GLASS HONEY-TUMBLERS: FRIEND J. A. ABBOTT'S PLAN.

I notice in your last number an article on sealing honey-tumblers, etc. This reminds me of a plan I devised and exhibited at our London show a few years ago, and for which I was awarded a special prize. Instead of warming the glass I just gave the edge a rub on a stone sprinkled with sharp sand, which almost immediately gave it a "tooth" to hold the wax. The edge was then dipped in a mixture of equal parts of wax and rosin. I found this mixture much better than wax alone, as it stuck much tighter and never cracked. I prepared some sheets of nice thin paper by dipping them into hot pure beeswax, though sometimes I covered one side only by floating the sheets on the wax. When cold, these sheets were fixed on top of the jars by about the same process as you often use to fix foundation in supers, but much less rubbing is required. Just passing the handle of the knife over once was sufficient. The sharp edge of the blade was then run round, and the air-tight and

natural honey-sealing was complete. If the glass was not roughened a little, the wax was liable to leave it after a little while, but the wax edge and the paper never parted after they had once met. It is possible your correspondent, Dr. Mason, may have read some description of this plan, which I fancy was described in the *British Bee Journal*.

J. A. ABBOTT.

Beeton, Ontario, Can., Dec. 29, 1886.

A FEW MORE POINTERS ON INTRODUCING.

There are a few points about introducing queens that Ernest did not give in connection with this subject in a late issue of GLEANINGS, which I should like to know. 1. Is it best to introduce a queen, that has had a trip in the mails, immediately on her arrival, or wait a few hours, or until the next day? 2. If you wish to exchange queens in a hive, do you put in the new one at the time of taking the old one out, or do you prefer to leave them queenless awhile? If so, how long? 3. Do you put the attendant bees in with the new queen always?

A. A. FRADENBURG.

Port Washington, O., Dec. 23, 1886.

1. Put the queen, immediately after her arrival, directly into the hive. In fact, I think it will be much better than to wait awhile, as you suggest.

2. Very frequently we take out and cage a queen, and introduce another one in her place, at one and the same time. We once thought it better to allow the hive to remain queenless before caging another queen; but by the Peet process of introducing we have lately found no trouble in introducing a queen at once. We keep only Italians, and I am not sure you could do this with hybrids, Syrians, or Cyprians.

3. If you find attendant bees in a Peet cage, as you probably will in a great majority of cases, cage them and the queen together on the comb. I do not know that it will make any difference to us whether the queen is caged on a comb, with or without attendant bees.—Right here I will say to our readers, if any of you have a desire to ask questions on some topics connected with our own apiary, on which I have not fully enlarged, be free to write us, and your questions will be answered either in GLEANINGS or by private letter. ERNEST.

THE PRINCIPLE OF THE ALLEY TRAP NOT NEW.

Alley's drone-trap may work very well, but it is not new. I do not know who invented the first drone-trap; but in the year 1866 were different drone-traps in Germany in the market. I bought one of them in 1867 from G. Dathe, Eystrup, Germany. This trap was constructed on the same principle as the Alley trap. It had two different chambers—the first one, in connection with the alighting-hole, had a series of holes large enough for the worker-bees, but too small for the drones. A prolonged canal opened into the second chamber, made of wire screen, through which no drones, but worker-bees, could pass. This canal is for the same purpose as the wire cones of Alley's trap, but it was closed by a small piece of light cotton stuff which easily opened into the second chamber, but closed the entrance to the first one.

This wire screen could exclude the drones, but the queen could not be excluded with certainty. The screen was not exact enough, and the wires

did not stay in place all the time. About 1876 was the perforated zinc in use in Germany; and since that time drone-traps were made out of perforated zinc. The idea of catching a queen is not new either. W. Vogel, *Bienenzeitung*, 1880, p. 46, talks about one, but only in a short way.

Selma, Texas, Dec. 3, 1886. L. STACHELHAUSEN.

A LETTER FROM SCOTLAND: HEATHER HONEY.

We don't have so severe winters or warm summers as you have, neither have we such large yields of honey; but for all that we have managed to raise enough to bring it to one-third the price it was 4 years ago. At that time white-clover honey in 1-lb. sections brought 30 to 34 cents; now it scarcely sells at all. There is some inquiry for heather honey. I do not know whether you have any heather in America or not. I never saw it even mentioned in GLEANINGS. It is very dark in color, not so beautiful as clover honey; neither, to my taste, is it as fine. R. ALLEN.

Overtown, Dyce, Aberdeenshire, Scotland.

REPORT IN RHYME.

I have sat down, in order to fix
Out my report for 1886.
I began in the fall of '85
With all my colonies only five
I got all things ready, I trust,
And packed them away in good sawdust
All around, just up to the eaves,
And filled the crates with forest-leaves.
So I fed them up very strong,
For you know the winter is quite long.
So I gave them an abundance of food
To keep them from cooling or need
I waited till the elm and maple bloomed,
And other early flowers, with their perfume,
Were with sweetness filling the land,
Before I set them on their summer stand,
Which, after I did it was truly alarming
How soon they got ready for swarming.
About the time I was planting my corn
I wrote to a bee-man, Thomas Horn,
For a pure-blooded Italian queen,
And received as fine as ever was seen.
So I worked every day like a man,
But I at once adopted the Heddon plan:
For on having no after-swarms I was bent,
I say it will work all right and prevent:
For each colony increased but one,
And to take their honey was only fun
For just as sure as I'm alive
They made surplus pounds 25.
But I had nearly forgotten to tell
I reared several queens to sell.
And I have now fully organized,
What it is to have my bees Italianized.
They do not always appear to be so cross,
But just you come up and be boss.
They will let you take from them their store
Without stinging, and that's a fact
Thus any person can plainly see,
For honey and gentleness they are the bee.
That every lover of bees should keep.
Who wishes to produce good honey cheap
I weighed the stores of all my bees with care,
And found they had plenty and to spare,
On such stores I think they will thrive,
And all come out in the spring alive.
So, now, to you I must all confess
To whom I owe so much success.
Doofittle, Heddon, Chaddock; and A. I. Root,
Though named last, does not stand foot—
Of Hutchinson, C. C. Miller, and all the rest,
I can not say who is best.
But I have read Root's work, his A B C,
All the way from A to Z,
And GLEANINGS is the thing for me
To study while working with the honey-bee.
So I have all my bees packed again this year,
And will end my story right here.
So I will build a happy good-sucht,
Until spring reveals my prospects to light.

Pearson, Ohio.

E. B. HAUGHEY, 5-10.

HOW HIS WORSHIP, THE TOAD, WAS STUNG.

Two neighbors (brothers), formerly neighbors and scholars of Dr. Dzierzon, old bee-keepers, relate the following, to which they were eye-witness: A large toad, which they had often seen among their hives, came one afternoon out of his retreat, a small marshy place behind their apiary. He stopped in front of a hive, catching some incoming bees, when all at once he got stung on his tongue, which swelled up so quick that he could not with-

draw it, but hung swelled out of its mouth, looking very comical. He withdrew, not to be seen again. You know taxidermists skin and stuff toads sometimes. Although they have a thick skin, the moment you put a little common salt on their back they become very sensitive. F. J. M. OTTO.

Sandusky, O., Nov. 6, 1886.

FOUR COLONIES DEAD ALREADY: WHAT KILLED THEM?

Out of 18 colonies, 4 are now dead, they dying during this cold spell. The weather was only twice below zero, the first morning 1°; and the morning after, 9°. My bees are all in single-walled hives. All have honey enough. We had about 6 in. of snow. I didn't remove the snow from the entrances. When I discovered that they were dead I opened two of them. I found them clustered naturally, also all the cells in the cluster full of bees. It looked to me as though they were killed instantly, without warning or time to change position. They had honey in their sacks, so you see they didn't starve. According to Dec. 1st GLEANINGS they didn't smother on account of snow. I haven't meddled with them since cool weather began. I can't find any other bees dead in the neighborhood. I wish to know what killed them so early in the season. I may lose all I have before spring, if somebody doesn't tell me what to do. F. P. HISH.

Henton, Shelby Co., Ill., Dec. 9, 1886.

Friend H., it is very unusual for bees to die in the manner you describe, especially if they had sealed stores all round the cluster. The fact that you found honey in their sacks, is not sufficient. When bees get so nearly out of stores that they have nothing but unsealed honey, and cells containing some honey and some pollen, they often die something in the way you describe. There needs to be plenty of good sealed stores on all sides of the cluster, so that every inmate of the hive can have access to it easily. I do not know that I ever saw a colony die under the above circumstances, unless it was where the stores were evidently of so poor a quality that dysentery set in. It may be, however, that your bees gathered something poisonous; but I should hardly think you would find them dead as you describe, even then. I do not know how to suggest any remedy for such a state of affairs in the winter time.

A NEW HONEY-PLANT.

I inclose a package of sweet-melissa seed. See description of same by T. J. Burrill, in *A. B. J.*, Oct. 13, 1886, page 651. My bees, the past season, worked from morning till night on melissa growing by the side of spider-plants, only occasionally gathering honey from the latter. In hot dry weather they worked lively on melissa in preference to all other flowers, of which we have quite a large variety. If my bees do not work better on spider-plants next season than they did this I shall raise no more for them.

Carpenter's square, or figwort, which grows in small timber near the creek, is more attractive to them.

Melissa imparts a citron-like flavor to honey, which our people consider delicious. I have grown melissa since 1881, but have kept bees only two years, commencing with one colony as an experiment. I increased to 15 good stands with about 50

lbs. of honey to each hive, excepting three, which have fully 100 lbs. each.

I have not lost a colony yet, and I winter them in a cellar which is not very warm. I have had applications for seeds, from different portions of the U. S. and Canada. I believe there is nothing better; and if it succeeds as well in every locality as here, I shall be amply repaid for my trouble in introducing it. Please give the seed a fair trial, and report to me in due season. A. C. TYRRELL.

Madison, Neb., Dec. 4, 1886.

CLASS LEGISLATION.

God made man,
And man loves money.
God made bees,
And bees eat honey.
God made the earth,
The earth raises flowers;
We do not produce them;
So they are not ours.
The products of the mine,
The land, and the sea,
Should all to God's children
For ever be free
To take and use as they may have need,
Leaving the rest their brothers to feed.

The iron, the copper,
The coal, and the zinc,
Are the gift of his hand;
But who, do you think,
Would allow you to dig some.
In case you should wish
To make you a fire,
A shovel, or dish?

Now, Brother Miller,
Pray tell, if you can,
Why for God's gifts
We pay tribute to man.
What is this that we hear
About class legislation,
Contention, and strife,
All over this nation

About outdawns and lockouts,
Boycotts, and strikes,
Gould and Vanderbilt,
Russell Sage, and the like?
What makes those be called
The kings of the nation?
Echo says what,
If not class legislation!

Michigan City, Ind., Jan. 3, 1887. W. W. MALTHBY.

FROZEN BROOD.

I am satisfied that there is more than one phase of foul brood as described in the convention at Indianapolis. I have had brood die in the cell, and dry up, and it created a stench almost unbearable. Still, I gave those dead-brood combs to strong colonies of bees, and they cleaned them up and all went along nicely. No more foul brood there. I am satisfied that it was not foul brood as you have it, but some at the convention described it as foul brood in the dry state. I never saw foul brood in the pus form, as you gave the description at the Indianapolis convention, and also others. I have been troubled three times this way each time in the spring, after a hard cold winter. I claim it is frozen brood, and nothing else.

Martinsville, Ill.

WM. ST. MARTZ.

HIGH VERSUS THE LOW PRICE OF HONEY.

I have just read Dadant's article about the sale of honey, page 981. The trouble is, that the people who eat honey do not find it cheap. I sometimes buy honey, as my own bees are some distance in the country. I have always had to pay, at least 20 cents per lb. I am inclined to think, that, if people who like honey could get it for 10 cents per lb. or less, the consumption would be doubled or trebled. I speak of Cincinnati prices. I live there.

THOMAS HUNT.

Conway Springs, Kan., Dec. 21, 1886.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN ON BEES OR OTHER MATTERS, will receive one of DAVID COOK'S excellent five-cent Sunday-school books.

Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows: viz.: Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and

Part II. Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

CONDUCTED BY ERNEST R. ROOT.

THE BOYS' AMATEUR BEE-HIVE FACTORY.

I BELIEVE I have not told you yet much about Jimmie's playmate, Sam. The two boys, as you may guess, were fast friends. Their likes and dislikes were much the same. They both were of a mechanical turn of mind—at least you would think so if you were to take a look at Mr. Green's barn and fences—little toy windmills here and there, which they had made with their knives. Besides these they whittled, out of blocks of wood, boats that they were wont to sail in a tub of water. Such waves as those boats would stand! The boy who made a craft which would stand the most sea (tub-waves) was the best fellow. Then there was a great variety of other things which they made, such as only the genius of a boy can evolve, aided by his inseparable, ever-ready companion, a *jack-knife*.

Mr. Green, noticing the bent of their minds, and desiring to encourage it as well as to put it to some profitable use, entered into a contract with old Santa Claus. The terms of said contract, as drawn up by the lover of little boys and girls, ran in this wise:

—OFFICE OF—
SANTA CLAUS.
DEALER IN

—PRESENTS FOR BOYS & GIRLS.—

Terms strictly Cash.

N. Y., Dec. 10, 1886.

For the sum of \$6.50, received, I agree to deliver in the morning of Dec. 25, A. M., at the respective homes of each of the boys Samuel Green and James Brown, a chest of tools, said chest to contain a complete assortment of the best tools.

(Signed) Santa Claus.

Old Santa, even if he is old, you see writes plainly enough, even yet, for boys and girls to read. Jimmie's parents were too poor to enter into any such contract with Santa Claus in favor of their son. Sam's father, however, thought he could afford a chest for his neighbor's son, both as a reward for regular attendance at Sunday-school, and because Jimmie was a boon companion of his own son.

I need hardly add, that the contract was duly fulfilled at the day and hour, and that the boys were rejoiced—"Just what we wanted," they said.

"Where shall we have our shop?" said they, on Christmas morning when they had got together. "Oh! I know," said Sam; "our old barn-loft will be just the thing."

Thither the boys repaired, lugging along their chests of tools. The loft had been used for the storage of stray pieces of lumber, stove-pipes, boots, etc. On their arrival they found cobwebs and a general litter. Spurred by the thought of what a grand place this would be for a shop, the boys soon had it cleaned up,—rubbish thrown out, and the pieces of boards packed neatly away.

When Jimmie was putting the last board upon the pile in the corner, he exclaimed,

"My! what's yer pa goin' to do with all them boards? Did he say you might have 'em?"

"He hasn't said any thing about them yet. They were some that were left from the corn-crib, and we put them up here about a year ago. I'll go and see if we can have them."

So saying, Sam clambered down the ladder just in time to see his father, who was just starting for town.

"Say, pa, did you have any particular use for those boards in the barn-loft?"

"I declare, I had forgotten about those boards. If Santa Claus did not say so, I believe he intended that they should be the property of you boys," said Mr. Green, with a twinkle in his eyes that Sam understood. Sam needed no further hint, but hastened back to the loft.

"Did yer pa say we might have 'em?"

"He did not say so in just so many words, but—"

"Good!" exclaimed Jimmie, who took in the situation. "Won't we just have a picnic? We'll make carts and windmills—big ones I mean; by cracky! yes, and bee-hives!"

During the early part of the afternoon, with Mr. Green's assistance, the boys made a work-bench. When it was finished it was discovered that they had no vise.

I tell you, boys, said Mr. Green, at the Home of the Honey-Bees, Medina, Ohio, they sell a very pretty little implement of this description for only 15 cents. But how can you get the money to purchase each of you a vise? I have a pile of wood which you can put in the wood-shed, nights and mornings, after school. If you will pile it all nicely in the shed I will advance you the money now, and you can send for the vises to-day.

"Let's do it now, and have the job off our hands," said Jimmie.

"We shall hardly have time," said Sam.

"Oh, yes! both of us can do it if we work a little after dark. It's only 3 o'clock."

Sam looked at the pile of wood with some misgivings. He "never *did* like piling up wood."

When, however, Jimmie commenced to load up with an armful, Sam followed his example. Ere long the pile diminished very appreciably. When it came supper time, the boys were both loath to give up the job. They thought it "just fun." Sam could not tell just why he enjoyed it. After supper the boys worked more energetically than ever, meantime talking and planning what things they would make and do, whether they could make bee-hives, etc. As it grew dark soon, they worked by—the light of a lantern which Sam's sister had thoughtfully hung up. When the work was done, nothing would do but those boys must send for the vises before they went to bed. Sam's mother produced writing-materials; stamps were inclosed, and the order sent.

To be continued.

JUVENILE LETTER-BOX.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it!"

THE KITE, AND HOW IT FLIES.

The kite you sent, we think a beauty. It came safely. Mr. Mace put it together for me, and helped me to sail it. It went up like a thing of life.

CORA BLANCHARD.

Mt. Hope, Morris Co., N. J., Nov. 30, 1886.

HIVES MADE BY HORSE-POWER.

I am a little girl. Pa had 9 swarms this spring, and they increased to 15 this summer. He got about 550 lbs. of honey. Pa has a shop where he saws his lumber out, and makes his bee-hives. He runs the machinery with the horse.

LIZZIE J. DOTTERER.

Newtown Mills, Forest Co., Pa., Dec. 14, 1886.

A HIVE WITH GLASS ON THE BACK, AND WHAT THE SUN DID.

My father gave me a hive of bees, if I would watch his bees, and hive them when they came out. There was a piece of glass on the back of my hive, and the sun shone through and melted two of the combs down. Papa took the honey out, and the bees built it up again. Next year I will put the hive in the shade.

BENJ. F. STOUT.

A QUEEN'S HEAD THE WRONG WAY IN THE CELL.

My pa had 45 stands of bees, and I have one. Pa did not get much honey last season. The bees are in good condition for winter. Pa and I were looking at the bees, and we found some queen cells, and pa did not want them, so I pulled off one of them, and the queen's head was turned the wrong way.

EUGENE WILLIS.

Jonah, Texas, Nov. 26, 1886.

AN ITALIAN QUEEN FIVE YEARS OLD.

Pa has between 50 and 60 colonies of bees. They have been doing very well this summer. He had an Italian queen which was five years old. Last spring she died. I read GLEANINGS, and find it

very interesting. We keep the Brown Leghorn chickens. We find they are good layers. I have a pet pigeon named Charley Boy.

Cold Spring, Ky.

LILLIE LURKER.

EDWARD'S SWARM OF BEES.

One day I was going out to work, and I saw a swarm of bees. They were on a maple-tree, and father gave it to me. He said if I would take care of it I could have all the honey that they would make. I got about a quart of honey. It was a small swarm, and that is why I did not get much honey. I have them in the cellar now. I am going to try to do better next year.

EDWARD STOUT.

Brighton, Iowa, Dec. 27, 1886.

SAWING OFF A LIMB ON WHICH WAS CLUSTERED A SWARM OF BEES; RESULTS.

I am a boy 11 years old. My pa keeps bees. As he works in Vienna I have to tend to the bees. We live on a farm. The bees nearly stung me to death last summer. The bees swarmed and settled in the top of an apple-tree, and I climbed the tree and sawed off the limb, and the bees got after me and ran me through the cornfield. I have lots of fun skating.

FRED BELLEMEY.

Vienna, Ill., Dec. 28, 1886.

Yours is not the first instance we have had of the unpleasant results of sawing off a limb holding a swarm of bees. Always be careful about jarring the limb while sawing; and when the limb is nearly off, let it down easily with a pitch-fork, or, better still if you can, reach it with your hands.

COLD WATER FOR STINGS, ETC.

My pa's bees are in the cellar. He built a stone wall around his bee-cellar last summer, and made a cement floor. I wish I could come and see Huber, and blow the whistle too. Ma reads the letters to me, and I want to hear some more about Jimmy and Ted. When I step on a bee, I put my foot in water. One day last summer a bee stung me in my face; and when I told ma I was stung she said, "Well, run and put your foot in water;" and then I told her it was my face.

CHARLIE PALMER.

Hart, Oceana Co., Mich., Nov. 29, 1886.

Yes, if you come to Medina we will give you a chance to blow that big whistle.—Cold water for stings, I know, makes the place affected feel better, but I am not sure but that you would get along about as fast if you did nothing.—I haven't seen Ted for some little time. I suspect that Jimmie, although I haven't heard him say, does not care to have Ted tag him into their new shop.

SWARMING, AND WHAT THE BOYS DID.

One day when my brother came in from the field for dinner we were sitting on the well-bed, and my brother walked around toward the bees, and he hallooed out, "Oh! the bees are swarming! I was bareheaded, and my father was working in the tile-factory. I jumped up and ran all the way to the tile-factory and told my father. I started right back and ran all the way, and my father came, and then they began to settle in the garden on the peas and on the ground. Father took the smoker and drove them into the hive which he had set close by. It was very hot, and we cut some bushes and laid them on the hive to keep the sun off, and they stayed in the hive.

WILLIE HUNT, age 12.

Dodson, Montgomery Co., O., Dec. 21, 1886.

A LITTLE GIRL TELLS HOW SHE PERFORMED THE
FEAT OF TAKING A SWARM FROM THE
"TOPEST" BRANCH OF A TREE.

In spring my father had 19 colonies, and increased to 49. He sold one this fall. They are all in good condition. He has them mostly in chaff hives. We sold over 600 lbs. of honey. I help pa sometimes when the bees swarm, and when he takes the honey from them. I hived but one swarm this summer, and that was on Sunday, when pa wasn't at home. The swarm got on the "top-est" stem of the highest tree. I did not know what to do. I called my sister. There was a wagon standing below. I climbed up the tree and sawed off the stem. The bees all fell on the tongue of the wagon. After I got down the tree we stood the hive beside the tongue and brushed the bees in the hive. We got them in nicely, but I got stung, and my sister too. I was stung "pretty" many times, but not as many as my sister. Her face swelled so hard that she didn't see any more in one eye.

DINA BLUNIER, age 13.

Roanoke, Ill., Dec. 23, 1886.

You certainly performed quite a feat in getting a swarm from the highest tree. I wonder how many boys could have done it. You deserve a chromo for that; and if your father didn't give you that swarm I think he ought to have done so. I will tell one of the clerks to pick out a large panel chromo and send it.

THE BEE, AND WHAT IT IS.

The bee is a very busy creature. There are two kinds of bees—the black and Italians. They put the bees in hives, and when the hives get so full of bees they will swarm, and sometimes they will swarm twice a year. We had a hive of bees, and other bees came and took all their honey. I and papa saw a bee in a tree, and I got stung on my lip. It swelled up one inch. The bees make honey in summer, and they live on honey in winter. Some folks have two dozen hives of bees. The bee honey is good. When I was down at my grandma's I got as sick as a dog on honey. The bee has a stinger. I ought to know, for I got stung with them. I don't know how many times I got stung. I could not tell or count how many times. The bee has six legs and two wings. The bee has two eyes. I don't know what the colors are of the eyes. Its back is yellow; not all the back either. At the end of the stinger it is black. I don't know where they carry the honey. CHESTER TURNER.

Brookville, Ohio.

Your notes on the bee are not all of them correct, but I suppose enough so for all practical purposes for the little folks. It would be hard to tell just what is the color of a bee's eye. Through a microscope they look as clear as crystal, but without any microscope they look brown. Perhaps you know that those big eyes are compound. For a fuller talk to the little folks on this subject, I would refer you to p. 42, in the year 1885.

THE POLLY OF STANDING IN THE WAY OF FLYING
BEES.

Papa has 12 colonies of bees. In the winter time he puts on an outside shell, much larger than the hive, and fills the cavity between that and the hive with sawdust or dry chaff.

I will tell you something that happened once

which seemed funny to me, but I presume it did not seem so to papa at the time. There was a storm came up, and the bees hurried home, angry as could be at being interrupted at their work. Papa happened to be standing in their way, and they all rushed up on him and stung him badly.

Frankfort, Mich.

LORA MARBLE, age 11.

It is not wise to stand in front of the entrance, or where you would be liable to obstruct the flight of the bees. A coming storm will start the bees home in great droves, but I hardly think the bees you speak of were angry because the storm interrupted them, but because your papa stood right in the way. When I am in a great hurry to get on the train it makes me clear out of patience to have some great big heedless man block the only passage to the car-steps.

WORKING WITH BEES* AFTER DARK, BY MEANS
OF A DARK-LANTERN.

Tell Ernest to try one of those dark-lanterns for working with bees after night. They are the best. I hold one for pa when he works with his bees after night, and the bees don't fly after it. It is so bright it hurts their eyes. I help pa find the queens. He has 100 stands of bees. We have two carp-ponds. The little fish will eat out of my hand. I have two nice big cats that catch the mice in the bee-yard for pa. ANNIE M. HAINES.

Moons, O., Jan. 5, 1886.

Why, Annie, you have given us quite a valuable item as to the value of a dark-lantern. I can imagine nothing nicer, when working with bees after dark, than to have a bright little girl "shoot" the rays of light from the bull's-eye lantern right on the combs, or wherever else it may be needed. I will try it the coming season, and try to report on it. I will tell the clerks to send you a panel chromo.

THE BEARS AND THE HONEY.

I inclose a piece of poetry which I copied from one of papa's books, "A Grammar of Six Different Languages." I think we had better not do as the bears did.

As two young bears in wanton mood,
Forth issuing from a neighboring wood,
Came where the industrious bees had stored
In artful cells their insidious hoard.
Overjoyed they seized with eager haste,
Luxurious on their rich repast.
Alarmed at this, the little crew
About their ears, undistinct flew.
The heads, unable to sustain
The unequal combat, quit the plain
Half blind with rage, and mad with pain,
Their native shelter they regain.
There sit, and now disreeter grown,
Too late their rashness they bemoan;
And this by dear experience gain,
That pleasure's ever bought with pain
So when the golden baits of vice
Are placed before our longing eyes,
With greedy haste we snatch our fill
And swallow down the latent ill.
But when experience opens our eyes
Away the fancied pleasure flies.
It flies—but oh! too late we find
It leaves a real sting behind.

Sonora, Ohio.

BERTHA JONES, age 11.

Thank you, Bertha; your little selection of poetry is real good. There are too many of us—yes, and little boys and girls, who behave ourselves very much like the two young bears. But we folks don't always profit by our experience, bitter and full of stings though it may be.

TOBACCO COLUMN.

SOMETHING FROM THE ST. LOUIS JOURNAL OF AGRICULTURE ON THE TOBACCO QUESTION.

FRIEND ROOT:—I don't know whether I am taking a liberty in thus familiarly addressing you; but the good turns you have unconsciously done me in furnishing in GLEANINGS the bee-lore I have found so necessary to my purposes have certainly constituted you my friend. I write a brief line to commend your good work in fighting the use of tobacco. I was very much struck with the facts related in the Dec. 15th No., by T. B. Terry (the picture of whom, by the way, is a good one, though a little too solemn-looking); certainly the considerations offered by Mr. Terry ought to be sufficient to induce every married man, if not every man, to give up the tobacco habit. But, unfortunately, to give up the confirmed use of tobacco is a most difficult thing to do. It is true, that I had the nerve to do so, some thirteen years ago, when I found that the use of it was exceedingly disagreeable to my then sweetheart, now my wife. But I think it must have been easier for me to do than for most people. I have known men to make honest endeavors to give up tobacco, and suffer so much that they concluded that the use of it was the lesser evil.

Now, since this is the truth, that the tobacco habit once formed is one that is exceedingly difficult to break, ought we not all to make a greater effort by individual precept as well as example to discourage the use of it by children? Mr. Terry's suggestion, to have a national law, is hardly feasible however desirable. There is but little disposition to enact sumptuary laws, whether relating to tobacco or whisky; but if every father of boys did all he could personally to prevent the tobacco habit being formed by his sons before they become of age, it is hardly likely that, on arriving at years of discretion, they would begin it. As for myself, I have tried to impress upon my big boy that it is a wretchedly poor specimen of manhood that requires to be bolstered up by either smoking or chewing. That, of course, is the temptation to boys. The boy's greatest ambition is to be a man, and appear manly. In his ignorance he is apt to mistake for manly things the swagger and loudness and disgusting habits of roughs and bullies, especially if any of these habits are indorsed by the example of his own father. Let us all do what we can to teach boys that the best and most courageous manliness is that which is founded on virtue, not on vice.

The case of fatal poisoning by tobacco, mentioned by Mr. Terry, is terrible, but no such extreme case ought to be necessary to make every man who has a decent consideration for others to leave off a disgusting practice. As disgusting as is to me the nicotine-laden breath of men with whom I have only business relations, how much more have I thought would mine be to my wife and my little daughter, when they offer the kisses of affection from their clean, sweet lips! There has been no time in my more than twelve years of married life when I thought the solace offered by tobacco could be worth the one-hundredth part of such evidences of affection; and since I should very surely refuse to kiss my wife or daughter if she used tobacco, I should find no justification for expecting

any thing else from them if I did. As a fighter against tobacco and whisky, you may count me a member of your band always.

St. Louis, Mo., Dec. 20, 1886. GEO. B. MORTON.

Many thanks, brother, for your hearty coöperation in this work that lies before us; and may we hope to find every now and then a similar stirring exhortation in your own journal. And, by the way, why can't you and other brothers of the press start in your own journals something like this?

"Any reader of the *Journal of Agriculture* who will give up tobacco because of what has appeared in these pages in regard to the matter, may have the journal one year free, he to give us a written promise to pay us for the journal whenever he shall yield to the temptation, and touch tobacco again in any form."

The letters from those who give it up are to be published as fast as received, for the encouragement of others. The objection has been made, that this is hiring people to do right; but the amount in question is so small it is usually taken more as a piece of pleasantry, and it seems to have the effect of appealing in just the right way to get a good many to get up and shake themselves, and start out in something they have for years known ought to be done. As the resolution and promise come out in a public journal, it is pretty well published and understood in any neighborhood, and few men will care to be seen using tobacco after they have in this public way announced the determination to give it up. It is like giving testimony in prayer-meeting—it strengthens and encourages others all along the line.

I have stopped smoking, and will promise you not to do so again. If you will send me one of your smokers, and I commence using the weed again, I will send you the price of it.

Phila., Pa., Oct. 18, 1886. JOS. B. CREAGER.

I see in GLEANINGS that you said any one who quits the use of tobacco would receive a smoker. Please send me one; and if I use tobacco again I will pay you for the same. MATTIE SCHEIERN.

Wayland, Mich., Oct. 11, 1886.

CLEARNS HIS CONSCIENCE.

I have broken my pledge. I quit using tobacco on bees, but still smoke once in a while. When I came to rake up my conscience I found that I owe you 50 cts. for the smoker you sent, although it was worn out long ago. You sent it with other goods. J. T. FLETCHER.

Clarion, Pa.

HAS USED THE WEED ALL HIS LIFE.

I have been using tobacco in various forms all my life until the past six months. I have now abandoned the weed altogether. Seeing your offer in GLEANINGS, I write to know if I am entitled to a smoker. I am very willing to pay the price of the smoker should I ever use tobacco again. I have 5 stands of bees. E. B. JOHNSON.

Manatee, Fla., Nov. 18, 1886.

OUR HOMES.

And if any man will sue thee at the law, and take away thy coat, let him have thy cloak also. And whosoever shall compel thee to go a mile, go with him twain.—MATT. 5: 40, 41.

LAST Sunday afternoon I found another added to my class in our county jail. He was a stout, ruddy-faced young man perhaps twenty years of age. His face flushed when I spoke to him, and I saw that he was quite bashful; but in a little time we got to talking like old friends. Robert's story was something like this: He came from England about two years ago, and had been traveling about here and there, trying to find work wherever it was to be found. His last job was on the railroad; and on account of reducing the number of hands in winter, he was thrown out of work, and had been vainly trying to find something to do in one of our neighboring towns. A few evenings ago, the man with whom he boards came home somewhat intoxicated. He seemed to be in a quarrelsome, fault-finding mood, and, among other things, he inquired of his wife where Robert was. She told him Robert had gone somewhere to help somebody deliver some goods. He then inquired if Robert had found any work yet; and when told he had not, he broke out with something like the following:

"Well, he is a lazy, good-for-nothing shiftless fellow. He certainly could get work if he half tried."

More remarks followed, not very complimentary to Robert. Now, the truth was, Robert had come home unknown to the folks, and was at that time in bed; but as only a thin board partition separated him from the family, he heard every word that had been spoken, and up he jumped and confronted the man who was speaking ill of him behind his back. I presume some hard and loud words ensued; and finally the intoxicated man drew a pistol. At this, Robert put his hands on the man's shoulder and pushed him away. This gave an opportunity of making a plea of assault and battery, and the boarding-house keeper went for a constable. The constable at once told him he was intoxicated, and refused to make any arrest. The man then went to another officer of the law, who was not quite so particular, and Robert was arrested, and called upon to pay a fine of \$6.40. Robert had not any money, so he could not pay it, and that is why I found him in jail that Sunday afternoon. You may perhaps notice that the above statement is Robert's story for it. I have not heard the other side at all, and, in fact, we do not care anything about the other side just now. When I find these boys in jail, I endeavor to get the full facts in the case, so far as I can, from their own lips, and then I endeavor to show them that, according to Bible teaching, they are condemned by their own words. Robert claimed, as almost all do who get into jail, that he was entirely innocent, and had done nothing. When I had questioned him fully on all the points of the case, I began talking with him somewhat as follows:

"Robert, why did you not stay in bed,

since you had once retired in good order, and thus have saved all this trouble and expense?"

"Why, Mr. Root, do you suppose a man is going to keep still in bed when he hears somebody calling him a good-for-nothing shiftless fellow, and going on in that way behind his back?"

"To be sure, I do expect a man to do just that very thing, Robert."

By this time my fingers were on the Bible, and I opened to the fifth chapter of Matthew, and read:

But I say unto you, Love your enemies; bless them that curse you, and do good to them that hate you.

Again I read:

But whosoever shall smite thee on the right cheek, turn to him the other also.

Robert previously said that he was a member of the Church of England before he came over to America, and therefore I expected to have him at least respect these words of the Savior, that seemed so especially calculated to help us to keep from getting into quarrels or dissensions. To my surprise, however, he promptly rejected all such teachings, saying, "If that is Bible, I don't want any of it around me."

I appealed to one of the other inmates, with whom I had had many long talks, and I expected, of course, he would say that the best thing Robert could have done was to have kept still and let it go. I turned to him. "Mr. Brant, if you heard somebody talking about you in the way Robert has mentioned, after you had retired for the night, would you not have kept still and let it all pass?"

"To be sure, I would *not*, Mr. Root. I would get up and teach him manners."

"Even if it resulted in bringing you to jail?" suggested I.

"Yes, even if it brought me to jail. I don't allow any man to abuse me when I am around to hear it."

I labored with them long and earnestly. I even went so far as to tell them I feared they would be in jail all their lives; but they decided they would take the jail, rather than submit to being "run over," as they termed it. Finally, however, I *did* succeed in getting them to admit, that, if a man *could* submit to be snubbed and abused, without saying a word back, or doing any thing, it would probably save trouble in the general machinery of human life.

"But, Robert," said I, "after the decision had been made, that you were to pay \$6.40 for laying your hands on a man before he touched you, why did you not pay it and have it done with?"

"Why, Mr. Root, I have already told you that I hadn't any money. You know I have not had any work all winter."

"But, it is a sad thing to get into jail, and have it hanging over you all your life afterward. Had you not an overcoat or watch, or something you could leave with some friend in order to keep you from going to jail?"

He finally admitted that he had a watch, and that it was worth \$6.40 a good many times over; but when crowded, he replied,—

"But, Mr. Root, *I was not guilty*. There was no assault and battery about it, and I won't pay it, and that is the long and the short of it."

I looked at my Bible quickly and read the following:

If any man will sue thee at the law, and take away thy coat, let him have thy cloak also; and whosoever shall compel thee to go with him a mile, go with him twain.

Robert said, as before, that he did not propose to come down to any such course of action. He fairly and squarely, when pressed, rejected the words of the Savior. This, in fact, was exactly what I wished him to do; or, in other words, I wished to have him *confess* that the reason why he was brought to jail was because he rejected Christ; and in rejecting Christ he had rejected and *defied* the laws of our land.

In presenting the subject to others as I have presented it to you, dear friends, I have been pained and startled to hear so many decide that Robert had done right—that is, if the facts were exactly as he stated them. I am afraid people are thoughtless, many times, in deliberately deciding to refuse to obey our laws. When I told the story at the noon service, and submitted the question to those gathered there, those who answered first, every one of them, thought that Robert did right in refusing to pay the fine imposed upon him. After a little more thought and reflection, finally several suggested that it was better to pay the fine than to go to jail, even though the fine was unjust, and the party innocent.

We now come to the point of considering the laws of our land. No doubt they are imperfect, and, many times, through false representations of evil men, the fines imposed are unjust; shall we therefore refuse to abide by the decision of the law? God forbid! Perhaps I have, at different times in my life, counseled disobedience to the law; but I am beginning to think I made a mistake. Are we not, dear friends, in danger of arraying ourselves with rebels and anarchists when we thoughtlessly counsel disobedience to the laws we have? I told the boys I would have paid the fine, even if I had had nothing to do with the matter whatever, but that I would have done it under protest, and so informed the officers, and declare I would have redress, if it were possible to do so; but that, for the sake of preserving the majesty of the law, I would submit to whatever it might decree. I think, dear friends, this is safe and sound doctrine.

I did not tell Robert at the time, that I felt quite certain, if his life had been just what it ought to be, he would not have been fined nor taken to jail, but I asked him if he had been in the habit of attending church while here in America. He admitted that he had not very much. I asked him if it was not true that he was sometimes in the habit of drinking intoxicants, as well as the man he boarded with. He admitted that he was in the habit of drinking beer; and although I may be mistaken, his face seemed to indicate that he was given, at least somewhat, to such habits.

Now I want to say to the young friends who may be reading this, that there is very

little danger that any of them will ever get into trouble such as I have described, if they are in the habit of associating with Christian people, attending church, Sunday-school, and the young people's prayer-meetings, wherever they happen to be located, and deporting themselves in a decent and respectable way, such as young Christians are almost sure to do. When I asked Robert if he could not get \$6.40 to save him from jail, he said he had no friends at all. It seems to me a young man is at fault in having no friends, even if he has lived only one winter in a certain locality. In our town there are good men and women—yes, young men and young ladies, who make it their business to look up strangers, and invite them to our meetings, and who try to call them in wisdom's ways. The trouble is, I fear, that those who complain that they have no friends are seeking ways of darkness rather than light.

Now a word to those who are not in jail and not in trouble; that is, not any such trouble as Robert has found. Yes, and I think I may ask for a word to professors of religion, and those who are members of our churches. Have you faithfully followed the words the Savior gave us in our opening text, in your own walks and life? If an enemy should undertake to sue us at the law, and take away a coat, what would be our attitude? How many of us are there who would be willing to give the cloak also, for the sake of peace, unless, indeed, our attention had been called to it by these words? Of course, I do not refer, nor do I think our Savior meant to have reference to highway robbers, such as I spoke to you about in our last issue; but these words were spoken to a class of people who were for the most part, at least, *friends* and *neighbors*—those who had permanent places of abode, and were considered respectable citizens. Why should such go to law? Why should we have *difficulties* and hard feelings with our friends and neighbors? Why should we waste time and money enough on some little unimportant matter to have bought a dozen coats, before the thought even occurred to us of letting the cloak go too, for the sake of peace? If we are compelled to go a mile out of our way to do somebody a service, are we not more apt to grumble than we are to show a readiness to go *two* miles? The Savior's injunctions seem to be to the effect that, if we are to be his followers, it is our duty to do a little *more* than just what we agree to do, or a little more than what we are in duty and justice bound to do. Sometimes I am told that a man would never get along in the world if he should undertake to get a living in that way; but such replies have always made me feel sad. Those who have read GLEANINGS a good many years, especially those real good friends who have been sending me such good kind cheering words during the past few weeks, know that I have tested these teachings just a little. Occasionally, when the spirit seems to be on me, I have done a little *more* than I was asked to do. I have given smokers to those who have stopped using tobacco, etc. Now, of course, you know I do not say this boastfully; but I mention it because I wish to prove to you

that a man will not get *poor* in following Christ's teachings. I have been many times surprised *myself* to see how quickly these things swing around and shape themselves. The one who follows Christ's teachings, and who tries to do it in the real spirit in which Christ gave it, seems to have *strange streaks of luck*, as it were. It hits people a little unexpectedly; and by some strange law that is past divining by our feeble intellects, the evil spirit is driven away—the enemy is disarmed, and hostilities are at an end. You just try it some time when you get into a discussion in regard to a small matter about the justice of a thing. When you see your opponent is honest, but mistaken, good-naturedly give up to him, or give him twice what he asks, if necessary, for peace and harmony. If he insists on your going a mile out of your way, say, "Why, yes, my friend, come to think of it, I will go *two* miles. I do it gladly, too, because it is according to the Savior's teachings." A certain class may laugh at you, and call you a fool. They may tell you that, if you undertake to go through life following out that plan, you will get into the poorhouse, and such like talk. But I tell you, you will not do any thing of the kind. There is a text in the fortieth chapter of Isaiah, that hits the point. It reads thus:

But they that wait upon the Lord shall renew their strength; they shall mount up with wings as eagles; they shall run, and not be weary; and they shall walk and not faint.

OUR OWN APIARY.

CONDUCTED BY ERNEST E. ROOT.

POSITIONS WHEN AT WORK OVER HIVES.

DID you, dear reader, ever have the backache when at work over the hives, lifting heavy combs, in a position somewhat cramped? Did you not sometimes indulge in a good stretch of the body to its fullest height? I have wished once or twice that the hives were on stilts, so that I could work at the hives when standing erect. If I remember correctly, W. Z. Hutchinson, when I visited him, did have his nucleus hives elevated. Our readers will also remember that some years ago we illustrated Dr. O. M. Blanton's apiary. A notable feature about it was that his hives stood on stilts. I believe, however, the majority of the bee-keepers prefer to have their hives on the ground, for reasons which I will not take space to enumerate here.

I sometimes examine, or "go through," 150 colonies per day. To accomplish the work as easily as possible, and at the same time relieve myself of the tedium of one posture when at work over the hive, I have recourse to a frequent change of position. The one I usually prefer is the one illustrated on page 31, last issue. Perhaps you think that such a seat as a hive-cover would hardly be stable enough. Just as much, and more so, than the ordinary milk-stool. You will see, by referring back to the cut, that it permits of an erect posture of the back. When it is desirable to get at or lift out a frame on the

outside of the hive, an inclination of the body, together with the hive-cover, puts the operator within easy reach of said frame. As far as possible, I aim to avoid any curving of the back, or the stooping-over of the shoulders. The inclination of the hive-cover one way or the other, as you will see, regulates the distance to any desired frame without the necessity of bending the back. A regular tool-box, or stool of four legs, will not permit this rocking motion, as you will notice.

When I feel as if I should like a change of posture I kneel in the soft grass (if not wet), my knees almost touching the side of the hive. After I have taken out a frame I drop back on my heels, if I desire to examine the frame for any length of time. About half the hives in our apiary are chaff hives. I can work over these best in a standing posture. As the chaff hive is two stories high, it is rather inconvenient to work with it while sitting or kneeling. However, I do sometimes sit on the edge of a chaff-hive cover; but as the rims of the latter are made of only $\frac{1}{2}$ stuff, I generally stand.

Perhaps some one of my readers will say, "I can't afford to sit down when at work among my bees." I reply, that it depends upon what kind of work in the apiary you are doing. If you are running for honey, then I think I can agree with you for the most part; but if your apiary is devoted to queen-rearing, as is ours, then it becomes necessary to spend some little time over a hive; as, for instance, hunting for a virgin queen, cutting out choice queen-cells, etc. In any event, we ought to avoid curving the back any more than is necessary, whether sitting or standing. I believe the instruction of the writing-teacher to his pupil, to "hold the body erect," is equally applicable to the bee-keeper engaged in rearing queens.

HOW TO HANDLE FRAMES.

To look at one side and then the other of a comb, becomes almost a necessity in queen-rearing. To revolve by the corners a frame full of honey, requires some little strength of the wrists—that is, if the top-bar as the axis of revolution remain horizontal. By turning the top-bar to the perpendicular, the frame may then be easily revolved. I throw out this hint for the benefit of beginners. The veteran bee-keeper will in all probability have acquired the knack intuitively from his long experience. The engraving on page 31 shows the operator in the act of revolving the frame. He is hunting for a queen which had been introduced a few days before. Having loosened the cage, wherein the queen was confined before the bees gnawed to her, he has thrown it upon the ground, which striking with some little force has jarred out a few bees that always collect inside. The bees thus shaken up take wing and return to the hive. Desirous of noting how well the queen has laid, he is in the act of revolving the frame, as I have before described, that he may see whether the queen has filled the other side of the comb with eggs also.

OUR OWN APIARY AT THIS DATE.

At this writing we have had a week or ten days of steady cold weather, the mercury

dropping frequently to zero, and several times six or eight degrees below. If this weather continues much longer I am fearful of the results among our bees. As I stated in Nov. 1st GLEANINGS, I did not then entertain a very hopeful view of the situation—foul brood having reduced our bees. If we had colonies instead of nuclei, I should have no serious apprehensions, even if the weather did continue to be cold.

REPORTS ENCOURAGING.

FROM 68 TO 96, AND 2400 LBS. OF HONEY.

I COMMENCED the season with 68 stands; increased to 96, and took 2400 lbs. of comb honey, nearly all white, which is a trifle over 35 lbs. per colony. This encourages me, as I see Doolittle did no better than I. They are all packed on their summer stands, with nearly one-half under the snow, out of sight, where I shall let them remain, as I know from experience that they are all right, for they drift under in the same way each winter, and always come out as bright as a dollar.

M. T. WILLIAMSON.

Covert, N. Y.

A GOOD REPORT FROM ONE OF THE PIONEERS.

I have sold over 11,000 lbs. of box honey from 80 hives last spring.

GAIN R. SMITH.

Victor, N. Y., Nov. 29, 1886.

108 GALLONS OF HONEY FROM 20 COLONIES.

I have 20 stands of bees, all in good condition. I did very well last summer. This summer I secured 108 gallons of extracted honey.

ALBERT CARTER.

Carrollton, Mo., Dec. 11, 1886.

AVERAGE OF 190 LBS. PER COLONY.

My bees gave me an average, this season, of 190 lbs. each, spring count; had no increase; the best season for honey I ever had, and I could have done better had I been prepared for the honey-flow.

CARBONDALE, PA. J. RUTHERFORD.

600 LBS. FROM 15 COLONIES.

I have had a pretty good harvest of honey—about 600 lbs., in pound boxes, from 15 hives. I took 98 lbs. from one swarm, and it swarmed 3 times this summer. I increased them to 40 swarms. Inclosed find one dollar for GLEANINGS. I have found that the money expended for it has been a profitable investment.

JACOB RICHARD.

Elmwood, Ill., Jan. 4, 1887.

HYBRIDS AHEAD.

I began the season with 8 colonies, increased to 21, and took 945 lbs. of comb honey. My bees are mostly hybrids, and they gather almost 2 lbs. of honey to the Italians one. I have one hive of the yellowest bees I ever saw, and they gather almost nothing in the sections, although they will fill a brood-frame quicker than any other bees I have.

Stark, Mich., Dec. 15, 1886. BENJ. PASSAGE, 8-21.

FROM ONE TO FIVE, AND OVER 350 LBS. OF HONEY.

My first swarm was pure Italians, purchased July 17, 1885. They gathered enough for winter stores, and I wintered them in a chaff hive of my own make after your pattern. They came out in fine condition in the spring. This season I increas-

ed them from one to five, by dividing, and one natural swarm, which came out late in September. The surplus stores amounted to from 350 to 400 lbs., besides leaving 10 full frames of honey in the lower stories, and 8 lbs. in the upper story, all in chaff hives.

FRANK FERRIS.

Mt. Clemens, Mich.

FROM 125 TO 208, AND 13,000 LBS. OF COMB HONEY.

My report for 1886 is as follows: I began the season with 125 colonies in fair condition; increased by natural swarming to 208, and have taken in all, 13,000 lbs. of comb honey, all in 1 and 2 lb. sections. The past season has been one of the best I have known in my 14 years' experience in the business.

Cambridge, Ill.

J. V. CALDWELL, 125-208.

AN AVERAGE OF OVER 200 LBS. PER COLONY, AND BLACK BEES TOO.

I commenced bee-keeping last spring. I bought 50 swarms, one of which deserted when let out of the hive, after being taken off of the cars, leaving me 49 when the honey season opened. I commenced extracting May 29, and stopped July 6, after extracting 9839 lbs. of honey, which was mostly from white clover. I increased to 81 swarms. The average per swarm was 200½ lbs. When they went into winter quarters they had 30 lbs. apiece. My bees are all blacks. They are in quadruple chaff hives. About the first of November I moved them about a mile. I had three teams, and two extra men, besides myself and horse, and it was all that six of us could do to lift them on the wagon. We moved them in half a day. They had a good fly the 11th and 12th of this month.

Brodhead, Wis., Dec. 20, 1886. P. H. FELLOWS.

ENCOURAGING WORDS FOR ALSIKE AND BUCKWHEAT.

I commenced the season with 60 colonies, spring count; increased to 100 colonies; got 2000 lbs. of honey in one-pound sections, and 500 lbs. of extracted, about half white and half dark. I worked some bees for my neighbors. I brought home my share of the increase, 15 colonies, making me 115 colonies to winter; 50 are packed in dry sawdust in chaff hives on summer stands; 65 are in the cellar. All are heavy with natural stores. The season commenced very early, but clover did not last long, on account of dry weather. Basswood did not bloom at all.

ALSIKE.

I had 16 acres of alsike clover. Bees worked on it early and late until the drought. It makes very nice hay for all kinds of farm stock. I sowed 16 acres this year, mixed with timothy. I sowed the silverhull buckwheat so as to fill up the gaps between other bloom as much as possible. I sowed one acre in August. Bees worked on it the most I ever saw bees on buckwheat. We cut it in the afternoon, and the next morning uncle Tom Frost had killed every thing so that the bees did not work any more. We drew the buckwheat into the barn, and thrashed it, and had 25½ bushels. This was getting three crops from the same ground in one season, as we cut about two tons of hay off before we plowed it for buckwheat. We think we got as many pounds of honey as we had of buckwheat from that ground. Taking the season together, it was very poor for honey.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, JAN. 15, 1887.

Unto every one that hath shall be given, and he shall have abundance; but from him that hath not shall be taken away even that which he hath.—MATT. 25: 29.

NEW names and renewals are coming in at a rapid rate. Thanks, friends, for your kind support.

FLAT-BOTTOMED FOUNDATION.

WE have just succeeded in making some beautiful flat-bottomed foundation send for; samples and prices. In weight, we believe it comes as near the natural foundation made by the bees as any thing we ever turned out. Mr. T. F. Bingham said he preferred the flat-bottomed foundation for sections.

CLOSED-TOP SECTIONS.

AT the Ohio Convention, when an opinion was called for, not one of the members present favored the use of closed-top sections, because it would not permit tiering up. Our readers will please take note, that this confirms the opinions expressed lately in the answers of our prominent apiarists, to the question-box department in a late issue of the *A. B. J.*

FOUL BROOD, AND FALSE ALARM IN REGARD TO IT.

ON page 10 of our last issue, friend Broers protests against a statement made in a former issue by one of our contributors, that foul brood was in the neighborhood. From a letter just received from friend McCamant, it seems the whole matter was only a hearsay. Their bees *died*, it is true, but probably from starvation, as friend B. suggests, and they *guessed* it must have been foul brood.

HAVING A SPACE BELOW THE BROOD-COMBS FOR WINTERING.

IN my remarks at the foot of friend Doolittle's article, page 976, Dec. 15, I omitted to mention that Mr. H. R. Boardman, East Townsend, O., has for years been a vehement advocate of this idea. Our readers will perhaps recollect him when I mention that I gave his portrait as "the man who winters bees without loss;" and, if I am correct, he has continued to winter his bees almost without the loss of a colony, year after year, although he counts his stocks by the hundreds.

VISITING THE HOME OF THE HONEY-BEES DURING THE BUSY SEASON.

A NUMBER at the Ohio Convention expressed to us their desire to visit, at some future date, the Home of the Honey-Bees, but that they would prefer to come and see us when we are in "full blast," and that, if they came during this time, they feared they would be unwelcome. To be sure, you would be welcome, dear friends. Come at any time; and if we are too busy to show you about ourselves, we

will see that some one does give you the proper attention. We have many visitors to our place every season, but we never have had too many.

GOING WEST.

MRS. JENNIE CULP, before leaving the convention, informed us that she would probably not be able to attend another Ohio State Convention; that she proposed selling her farm, apiary and fixtures, with a view of going west with her boys. She stated, that, after selling, she probably would not do much with bees. As the work in the apiary has now gone beyond her strength, and as she is not obliged to work for a living, she has so decided. It is with some degree of regret that we give this intelligence to the friends; but we hope that, when she is located in her new field, we may again hear from her through the columns of *GLEANINGS*.

MANUFACTURING COMB HONEY.

THE people who stick to the falsehood about manufactured comb honey have finally found a place in Chicago where a man could be seen sealing up the combs with a hot iron. They never saw him making the *combs* out of paraffine, but he was simply sealing them up. Our enterprising friends of the *A. B. J.*, when notified, made haste to see the sight. What do you suppose they found? A Chinaman near a window, ironing collars and cuffs with a flat-iron! Did you ever? Ernest suggests that I have forgotten to state that the innocent-looking laundryman had a cake of *beeswax* by his side, with which to polish his flat-iron.

SENDING DELEGATES TO THE OHIO STATE BEE-KEEPERS' CONVENTION.

A MOTION was carried at the Ohio State Convention, mentioned in another column, that we invite, through the columns of *GLEANINGS*, the county and district bee-keepers' conventions to appoint and send delegates to the State Convention to be held at Columbus, about a year from date. The object of this is to put the county and district associations into direct communication with the State association. We therefore earnestly request that the secretaries will see that this matter is brought properly before their respective bodies, and that the members may act upon it. We give you notice thus early, that all arrangements may be completed in time.

BEE-KEEPERS' PRICE LISTS.

OUR facilities for turning out first-class price lists and general job work were never more complete than now. If you have anything in this line, write us for prices and samples. Remember, we have a very large stock of wood cuts, especially for price-list work. The following have been printed at this office: A 22-page price list, apiarian implements and bees and queens, for P. L. Viallon, Bayou Goula, La.; a 4-page large-size list of bee-keepers' supplies for J. D. Rusk, Milwaukee, Oregon. The following have been sent to this office:

The first comes from C. M. Goodspeed, Thorn Hill, Onondaga Co., N. Y., Specialty, the leading papers and magazines; also Italian bees and queens' raspberry and strawberry plants, al-sike clover, poultry, etc.

A very neat 36-page circular has been sent us by James Heddon, giving nice drawings of his new shallow hive, and much important and valuable matter on various subjects. He also offers honey in attractive packages at very low prices.

A 34-page circular comes to hand from C. F. Muth & Son, Specialties, honey and apiarian supplies.

From E. T. Flanigan, Belleville, Ill., an 8-page list of bees, hives, fdn., small fruit, etc.

From G. W. Stanley, Wyoming, N. Y., a 12-page list.

SPECIAL NOTICES.

DISCOUNTS UNTIL FEBRUARY 1.

REMEMBER, we allow 4 per cent discount on all purchases of whatever nature, made between now and the first of February.

SIMPLICITY HIVES.

WE have been making some changes in our table of prices; and while it does not affect the price of a complete hive, we have been compelled to advance the price of bodies only, without rims or covers. Our boys have just made the discovery that we have been selling bodies only, for less than cost.

MAPLE SYRUP.

In view of the crop soon to come, we offer the remainder of the lot mentioned on page 1002, Dec. 15 issue, at 80 cts. per gallon, or 90 cts. with package included to ship it in. The new crop will be in market probably about March 1.

COPPER BATH-TUBS.

WE have found the manufacturers of the copper bath-tubs, referred to on page 884, GLEANINGS for Dec. 1, and are prepared to furnish a tub of 10-oz. copper, 5, 5½, or 6 ft. long, at an even \$12.00, f. o. b. in New York. The regular price is \$13.75. They are made in a neat wooden box, ready for use, and they can be set in the corner of your bath-room. They are furnished with a brass plug in the bottom, to let the water off.

THE ABBOTT HONEY-KNIFE.

We have just had a very pleasant visit from Mr. T. F. Bingham himself, resulting in an arrangement (paying him a royalty) in regard to the honey-knife, whereby we can sell them as we proposed, and have it satisfactory to all parties. We are satisfied, after having carefully examined the steel in friend Bingham's honey-knife, and in friend Abbott's foreign copy of it, that the Bingham honey-knife is greatly superior in the quality of steel. The Abbott knife, however, is a very good one for the money.

REDUCTION IN THE PRICE OF HONEY-EXTRACTORS.

In view of the close prices on almost all staples, we have reduced the price of our Langstroth honey-extractors to \$6.00 instead of \$7.00; and all sizes from No. 1 to No. 5 will be \$6.00. All numbers above 5 have been correspondingly reduced. Send for new price list. We have also made an important reduction in circular-saw mandrels. Our \$10.00 mandrel for holding a gang of 9 saws is now reduced to \$7.50; the \$6.50 mandrel to \$5.00; the \$4.00 mandrel to \$3.50; and the \$2.50 mandrel to \$2.25. Our mandrels were never better made than now, and are the same we are using every day in our wood-working department.

PERFORATED ZINC TO DEALERS.

As perforated zinc is proving itself a necessity to the best results in securing large crops of honey, and as the perforations in the zinc of our make are just right, according to the opinion of the Michigan Bee Convention, we have determined to offer dealers who advertise our zinc in their catalogues, a special discount. Our prices are as follows: 1 sheet, 28×96 in. (18½ sq. ft.), \$1.50; 2 or more sheets, 5 per cent off; 10 or more sheets, 10 per cent off; less than a sheet, 10 cts. per sq. ft. Ten honey-boards, 14×19½ for Simplicity or chaff hive, \$1.50; 100 or more, 10 per cent off; less than 10, 16 cts. each. These honey-boards have a margin of unperforated zinc all round, and have proven easier to remove from the hive than those with a tin binding. Zinc strips, ¾ in. wide and 18 or 19½ in. long, with one row of holes, to be used in the slatted wood-and-zinc honey-board, \$1.00 per 100; 1000 or more, 10 per cent off. To dealers who advertise our zinc we will give a discount of 25 per cent, the same as we do on extractors and metal corners. Write for prices on odd sizes of honey-boards. For 14 in. and under in width, and 19½ in. and under in length, in lots of 20 or more, the price will be the same as the regular boards; but over those measurements the price will be much higher, on account of waste.

HIVES IN THE FLAT.

WE have revised our prices of Simplicity and Portico hives in the flat. There is little if any change in the prices of hives taken as a whole; but where bodies or covers are taken alone there is a marked change. We have also given prominence to "Ten crates," as we call them, in the hope that you will save yourself and us much trouble by ordering regular packages instead of an odd number of hives. We have these regular packages all put up ahead; and when you send us an order we can very often get it off with more dispatch if you order regular packages than if you order odd numbers of hives. Please read the following on page 18 of our price list, instead of the tables of prices of hives in the flat given there. The cuts referred to in the following, you will find on pages 17 and 18 of our price list. If you have lost or mislaid your price list, drop us a postal and we will send you another.

SIMPLICITY HIVES IN THE FLAT (KNOCKED DOWN).

Also Portico Hives and a combination of the two.

See cuts on this and the preceding page. Hives in the flat consist of the material all shaped, ready to nail together. These include metal rabbets for the frames to rest on, but nothing else—no frames, sections, or inside furniture of any kind included at these prices. For brood-frames, see page 14. For sections and wide frames for holding the same, see page 25; comb fdn., page 8, and enamel-cloth sheets, page 10.

The Simp. hives are packed in what we call "Ten crates;" i. e., 10 Simp. bodies, 5 covers, and 5 bottoms, are packed in a crate. This makes five 2-story Simp. hives; but the bottoms and covers are made just alike, and interchangeable, except that the cover is a better board than the bottom, or has a sheet of tin on it to prevent its leaking. Thus you can use the bottoms for covers, making 10 one-story hives by supplying home-made bottoms.

The bottom is used the same side up as the cover, and stands on four half-bricks. The entrance is made by sliding the hive forward a little on the bottom-board. The alighting-board shown on page 3 is a valuable addition. With it the entrance can be contracted or enlarged as necessity demands, in different seasons of the year. Some prefer to make their own bottoms, and want 10 all good covers in their "Ten crates," and no bottoms. Others, again, prefer the ½-story cover shown on the Portico hive on this page.

Again, there are people that will have a hive with the old-fashioned Langstroth portico, and a permanent bottom-board, which the Simplicity hive has not. There are some very good reasons for such a preference, where hives are to be moved much; as into the cellar and out, or when they are to be shipped and sold. For these reasons and others, we make and keep in stock the Portico hive shown above. Some want the Portico hive for the lower story and a Simp. upper story with flat cover, like the one shown above. Others want ½-depth bodies for tiering up. Others, still, want their hives made of better lumber than that we ordinarily use, which is No. 2 stock boards. We desire to meet all these wants; and as a help to you as well as ourselves, we have devised the following table, giving the price of each piece in lots of 10.

Ten bodies must be taken to get the 10-rate, but 5 covers and 5 bottoms entitle you to 10-rate on each. You may order any combination that suits your taste and purpose, calling the articles wanted by the names given in SMALL CAPS, and giving the price.

TABLE OF PRICES.

Those who order less than 10 must add one-fifth to these prices to pay the extra expense of packing.

	Price of 10 in flat.
SIMPLICITY BOTTOM-BOARDS	\$1 00
" " WITH ALIGHTING-BOARD	1 50
SIMPLICITY COVERS	2 00
½-STORY COVERS	2 50
½-DEPTH BODIES	2 00
SIMP. BODY, NO. 2 STOCK BOARDS	3 00
" " " " " "	4 00
PORTICO HIVES, with permanent bottom, no cover	4 00
" " " " " "	3 50
TEN CRATE NO. 1, contains 10 Simp. bodies, 5 Simp. bottoms, and 5 Simp. covers, making five 2-story hives, in flat	\$4 50
TEN CRATE NO. 2, contains 10 Simp. bodies and 10 Simp. covers, no bottoms. Price of crate	5 00
TEN CRATE NO. 3, contains 10 Simp. bodies and 10 ½-story covers, no bottoms. Price of crate	5 50
TEN CRATE NO. 4, contains 10 Portico hives, with permanent bottom-board and ten ½-story covers	6 50
By combining ten crate No. 2 and 10 Portico hives, no covers, at \$4.00, you get ten Portico hives with Simp. upper story	9 00

We can make any other combination you desire, in the same way, because all are made interchangeable.

For 2 ten crates deduct 2 per ct.	For 8 ten crates deduct 6 per ct.
" 3 " " " 3 " "	" 10 " " " 7 " "
" 4 " " " 4 " "	" 20 " " " 8 " "
" 5 " " " 5 " "	" 50 " " " 9 " "

For 100 ten crates you may deduct 10 per cent.

Please order in regular pkgs. of 10 for even if you don't need the extra ones at the time, you soon will.

COVERS.

There are some very great advantages in having a cover flat on top, and plain and simple, made of a single board, like the Simplicity cover. It can be used interchangeably as a bottom-board; it permits the hives to be piled up like square boxes of merchandise; they can be shipped at less rates, because there are no projections and corners to be knocked off, etc. The disadvantages are that it is too shallow for wintering, without an upper story, or for a tier of surplus boxes; it gives little or no chance for ventilation; it can not be raised with one hand easily. As one cover can not well please everybody, and combine all these advantages, we furnish the one shown above. This cover is made with the thin roof-boards screwed against the under side of the ridge-board, and the holes thus left in the gable ends are covered with wire cloth, and serve as ventilators. It is of sufficient depth to cover a crate of 28 1-b. section boxes, or a good-sized chaff cushion for wintering, and can easily be raised with one hand by the ridge-board, because, except this ridge-board, it is all made of $\frac{1}{2}$ -inch stuff.

NO BEE-HIVE

Now before the public contains as many practical points for the profitable production of honey as

Shirley's Contractible Hive.

It admits of the use of from 1 to 10 frames, without extra fixtures. The most complete reversible frames, etc. Price \$2.00. Satisfaction guaranteed, or money refunded. For further information, address
W. H. SHIRLEY,
3-4-5-6-7-8d. MILL GROVE, Allegan Co., Mich.

Vol. XV.

FEB. 1, 1887.

No. 3.

TERMS: \$1.00 PER ANNUM, IN ADVANCE; 2 Copies for \$1.90; 3 for \$2.75; 5 for \$4.00; 10 or more, 75 cts. each. Single number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canada. To all other countries of the Universal Postal Union, 18 cts. per year extra. To all countries not of the U. P. U., 42 cts. per year extra.

DR. MILLER'S "T" SUPER, AND ITS USE.

DISCUSSED BY TWO OF OUR LARGE HONEY-PRODUCERS.

MR. EDITOR:—I inclose herewith a letter from one of the veterans, M. M. Baldridge. I think so interesting a letter should be given to the fraternity at large, and for their benefit I will also append my reply.

C. C. MILLER.

FRIEND MILLER:—The "spirit" moves me to write you a few lines about your "Year Among the Bees." I have read the book through recently, and some parts of it two or more times. Many things you say interest me exceedingly; and let me say here, but not by way of flattery, that you have written a very good work on bees. I have also read with especial interest what you say about the **T** super. I have made them since 1883, but not exactly as described by you. I use no iron pieces nor loose **T** tins. I simply saw through each side-piece 3 times, and then insert the wide edge of the tins, and drive two $\frac{1}{2}$ wire nails through both sides of each end. This holds the tins in place at all times. But you have the upright edge of tins only $\frac{1}{4}$ inch deep, and find $\frac{1}{2}$ too deep, as it holds the separator too high. I have not used the super enough to know how that is; but others tell me that the separator needs to be only $2\frac{1}{4}$ inches wide, when of tin, for the $4\frac{1}{4}$ -inch section; that is, a sheet of tin, 14 by 20, will make 5 separators, quite wide enough for the pound section; therefore for the nailed section I get the tins out 1 inch wide, and have the upright part $\frac{3}{4}$ inch high, as the top and bottom pieces of the section are $\frac{3}{4}$ inch thick. This gives an open space of $\frac{1}{2}$ inch at both top and bottom.

I also notice, that, with the **T** super, you prefer wood separators to any other material. Now, I wish you to tell me where you get the wood separators you use; what is their exact width, also thickness, for 16 sections, and what do they cost per 1000?

THE WIDTH OF SECTIONS.

I see also that you prefer two widths for sections.

I rather think I should prefer one width ($1\frac{1}{4}$ inch), and use separators between all, as I have no trouble to make bees go to work in them *at will* when in right condition. I like the *slatted* honey-board very much. I can, however, keep the queen, or brood and bee-bread, out of the sections, even when none is used. But how to do it is the "secret," and is known only to a few.

REPORT.

I have been up in Wisconsin the past season, keeping bees on shares, and returned only a few weeks ago. I had 178 hives in May to begin with—150 good ones, but the rest were weak. I closed the season with 230 good ones and 11,000 lbs. of honey—8,000 lbs. being in the comb, in Muth's sections, holding $1\frac{1}{2}$ lbs. each. These $1\frac{1}{2}$ -lb. sections were on hand when I went up there, in May last, and so I used them; but hereafter I shall use nothing but 1-lb. sections. Our hives in Wisconsin had 3 boxes each, holding 10 sections each, with no honey-board. We took 10 full boxes from some hives, and should have taken 15 to 20 thousand pounds of comb honey from all, if I had found things there as represented.

THE VALUE OF ALSIKE.

I had a deal of honey from alsike. The present owners of the bees sowed 90 acres of alsike, in September, by my directions, and I rather think they will have "lots" of honey next year. Alsike is the best honey-plant, all things considered, I know of; and when folks learn how to raise it properly they will quit fooling with other plants. Marvin has a "heap" of alsike growing a few miles west of this city, all secured by following my directions. There should be a thousand acres—yes, 10,000 acres—of it in the U. S. where there is but *one* now. I saw Marvin a few days ago. He says he would have had but little honey this year had it not been for alsike.

By the by, as you must have seen Betsinger's wire-cloth separators at Indianapolis, what do you think of the idea, when expense and all things are duly considered? Why would it it not be a good idea to have one-fourth-inch holes made through the wood separators, the same as open bottoms for

chairs? Still, this may be of little consequence, as I can force all the honey up stairs *at will*, anyway. With the Muth box it would be too much bother to use separators; still, I think it will pay me to use them hereafter. Again, I have by no means given up the idea that moving bees in car lots from South to North, in the spring, and back again in the fall, is a paying project; nor shall I abandon the idea until the matter has been properly tried. No one has ever yet tried the plan *properly*. I have now 150 hives at Yazoo City, Miss., which I intend to have filled with bees next spring. In May I shall move them up here somewhere for the white-honey crop. The latter part of July I shall take them to Wisconsin, where there is plenty to do on buckwheat and goldenrod during August and September. By this means I should secure 3 good honey crops in one season. What I shall do with the bees at the close of the season in October I do not know yet.

My hives at Yazoo City have two stories, with 10 frames in each—only 7 inches deep inside of frames. When ready for box honey I use but one set of frames, and use the top sets for new swarms or extracting. The hives were got up expressly for shipping bees from South to North and back again each year, so you see I have had plenty of faith in the project, and still have. The cost of getting a car-load of bees from Yazoo City or New Orleans to Chicago is about \$100; and as 200 stocks in 7-inch hives can be safely brought up in one car, the cost, you see, is only 50 cts. per colony, or \$1.00 both ways, there being no danger of any loss down South during winter; and the bees being able to double their number of colonies, or to gather a good crop of honey before May, I can see no good reason why they should not, while South, pay the entire expense of shipping both ways.

George Grimm has left our ranks. He writes me that the bee-business does not pay well enough to suit him, and is practicing law, having a good business. I am told that he was elected to the Legislature this month. M. M. BALDRIDGE.

St. Charles, Ills., Nov. 22, 1886.

DR. MILLER'S REPLY TO MR. BALDRIDGE.

Your plan of making 1 supers has advantages and disadvantages. It is no more work than my way, possibly less; it has the convenience of having the tins always in the right place in the supers, without the trouble of placing them every time and having them slip out of place, sometimes when putting sections in the super. The loose tins on the other hand, as I use them, admit of taking out the whole super full of sections *en masse*, and I can hardly imagine any way by which the sections can so easily be taken out with the fixed tins. Moreover, in putting the sections in the supers with loose tins, the tins adjust themselves to their places; and when the whole super is filled, the tins can not fail to be in exactly the right place. If the tins are fixed, it will require very exact workmanship to make the spaces between the tins exactly the same in every case.

You say, "Others tell me that the separator needs to be only 2½ inches wide, when of tin, for the 4½-inch section." I hardly believe it can make any difference as to width, whether the separator be of wood or of tin. In actual practice, I have found exactly the same difficulty with each, when too narrow. Whoever found 2½ inches sufficient, can hardly have a very extended experience, or else must have had such careful management that separators might have been dispensed with altogether. Now, we know that some succeed quite well without separators; and in case where two sections are built perfectly true without a separator between them, I think the intervention of a separator would make no difference, whether 2 or 4 inches wide. What I want a separator for is to force the bees, under any and all circumstances, to build the combs in sections so true that there will not be the least difficulty in packing. With the separator coming within ½ inch of the top or bottom of the section, this is accom-

plished; but an eighth of an inch more than this gives different results. You see, that ½ inch difference makes just one-third more open space than if ⅓ inch is allowed, for the wood of the section occupies ⅓ inch, leaving ⅔-inch open space. When this ⅔-inch open space is allowed, you can count on an unpleasant number of sections being built so as to project under the separator wherever a section has progressed much in advance of its neighbor, or in any case when work is going on very slowly. If the little projection were all, it would be a matter of less consequence; but this projection is pretty sure to be attached to the separator, and, when detached, the section "bleeds," and this has occurred with me, equally with wood or tin. So, for the 4½×4½ sections I want 3½-inch separators, so placed as to make the space alike at top and bottom. Wood separators of this width I get of poplar wood from the Berlin Fruit-Box Co.

I think, if you look again, you will not find that I prefer two widths for sections. On page 42 I say, "I have used a mixed arrangement with some degree of satisfaction," but I have more satisfaction in using only one kind.

I do not use the slatted honey-board to keep the queen out of sections, as I had no trouble in that direction before I used the slatted honey-board. Its great value is in preventing the bees from building bridges of comb between the brood-frames and the sections.

I believe alsike to be a valuable plant; but I have quit fooling with it, because I have found too great difficulty in getting a good stand. Probably better knowledge on my part would secure better results. It is open to the objection, that, with ordinary treatment, it blooms at the same time as white clover. Still, I am glad to see that some of the farmers about me are beginning to "fool" with it, and I shall be glad if they are more successful with it than I have been.

Without having tried them, the Betsinger separators strike me as a good thing, if not too expensive. I do not know what it costs to get them up. If the material is not so expensive as to prohibit their use, by manufacturing in large quantities he could make them so as to sell for less than any one else could get them up in small quantities, and still make a nice sum.

Your South-and-North project will be looked upon with much interest; and if you make a success of it I think you may claim to be the pioneer among the successful ones, for I take it that others will follow if you succeed. C. C. MILLER.

Marengo, Ill.

In regard to the width of separators, I think I am prepared to say, from actual experiment, that 2½ inches will not answer for the Simplicity section. As 14 inches is the common width of tin plates, we are in the habit of dividing this 14 inches into 4 parts, giving a separator 3½ inches in width. Now, it is possible that something a little narrower would be safe, and it may be well to go over this matter again, especially if we are going to use the exceedingly expensive material, wire cloth. Friend Betsinger said, at the Albany Convention, that 8 cents per square foot was as low as it could be furnished; and, if I am correct, he charges the same, whether a large or small quantity is used. The same kind of wire cloth has been in our price list for some time, for use in

carp ponds, drying fruit, etc.; and we find the price he has fixed is about as low as it can be figured. It is possible, however, that, if the manufacturers could be given a very large order, to be worked at their leisure, a little better figure might be obtained. We will ascertain in regard to the matter.

THE OHIO STATE BEE-KEEPERS' ASSOCIATION.

HELD AT COLUMBUS, O., JAN. 11, 12, 13, 1887.

THE meeting was a very interesting one, considering the small attendance, which was owing to the neglect of one of the officers in not giving proper announcement beforehand.

FIRST DAY.

On account of the small number present, an informal meeting was held.

SECOND DAY—MORNING SESSION.

Convention called to order with Dr. H. Besse in the chair. Minutes of previous meeting were read and approved. Treasurer's report received. The election of officers, being next in order, resulted as follows: Pres., Ernest R. Root, of Medina, Medina Co.; Sec. and Treas., Frank A. Eaton, of Bluffton, Allen Co. Other matters of business having been disposed of, by request of the association Pres. Root gave a talk on foul brood as it appeared in the "Home of the Honey-Bees." In brief, the address was as follows: The disease first broke out about the first of last July. He was not certain as to how it originated, but thought it was started by robber bees gaining access to a few kegs of honey which had been purchased some time before. The incipency of the disease was difficult to describe. A few affected cells appear in its early stages, and the larvae have a light coffee color; as the disease advances, the larva changes to a darker coffee color, like the coffee-berry, and finally dries up in one side of the cell. If a toothpick be inserted into an affected cell in its first stages, the diseased matter will adhere, forming a sort of string. The speaker stated, that during the past season they had had sixty cases. Each, as soon as discovered, was treated as follows: All the combs of the affected hives, after the bees were shaken off into a clean new hive, were consigned to the boiler-furnace. He thought it cheaper to give the bees a set of new clean frames filled with foundation, than to extract the old diseased combs, render out the wax, and boil the frames for use again. The diseased hives were then scalded out with steam. He was not sure but that the disease might appear again the coming year, but in no colonies so treated did the disease reappear.

After the speaker closed, Dr. Besse said he did not think it necessary to go to the great waste or expense of burning up the frames, combs, and honey. Why not extract the honey, render the wax, and boil the frames, and in that way save that which would otherwise be wasted?

Pres. Root thought there would be a good deal of risk attending such a practice—that robbers might gain access to the diseased honey and wax, while so working.

In this connection the advisability of purchasing honey to feed, instead of sugar, was opened for discussion. It was argued, that, as the former

might contain the germs of foul brood, it were better to feed sugar.

Mr. Goodrich.—Feed your own honey that you know is all right.

Secretary.—Suppose you haven't any honey to feed?

Dr. Besse.—Purchase your honey, and boil it. If 212° will kill the germs, I can see no danger.

Mr. Cole.—I think the practice of buying sugar to feed, is damaging to our trade. When people see you buying sugar they won't believe but that you intend putting it upon the market again in the form of honey.

After further discussion, in which the members of the convention were divided in their opinions, the convention adjourned till 1 P. M.

AFTERNOON SESSION.

The convention was called to order, with Pres. Root in the chair. A list of questions was handed in by S. R. Morris, and discussed in the following order:

1. How should a house be constructed to keep honey best, both in winter and summer?

Dr. Besse.—I keep it best in a dry house that does not reach either extreme of hot or cold.

Secretary.—Keep it in a honey-house that gets quite warm in summer and fall, then remove to some room in the house where the temperature does not go down to freezing.

E. Cole.—Do not keep it—sell it.

2. Is comb honey injured or made unsalable by freezing?

After some discussion it was generally agreed that the quality was not injured by freezing, but the combs are cracked by freezing, and thawing would cause the honey to drip.

3. Which is the best mode to control or prevent swarming?

J. W. Newlove.—I use single-tier crates, and give the bees plenty of room by tiering up. Put a crate upon the hive about ten days before the honey-flow starts. When the bees are thoroughly at work, and have filled the sections about half, raise the crate and put under it an empty one, and so on, giving plenty of room. I recommend this plan to my customers who are farmers. I find by this plan that bees seldom swarm.

Secretary.—It is an easy matter to control swarming when running for extracted honey, as a liberal use of the extractor will greatly control; but the difficulty comes in when working for comb honey. I have practiced, very successfully, extracting from the side combs in brood-chamber, placing them in the center. If the colony is very populous, remove one comb, placing an empty frame with but a starter in the center, thereby giving the queen plenty of room, at the same time putting on one tier of sections, then tiering up as fast as the honey-flow will warrant.

4. Will the drone progeny of an Italian queen be pure Italian, provided she mated with a hybrid drone?

No one present had any occasion to doubt the well-founded principles of Dzierzon and other writers on this subject.

5. Which is most profitable—to give a new swarm full frames of foundation, or only starters?

Dr. Besse.—I use starters only.

Pres. Root gave W. Z. Hutchinson's plan.

J. G. Ricketts said that Mrs. Jennie Culp used full sheets, and much preferred them.

MORNING SESSION—THIRD DAY.

After the convention was called to order by the President, C. E. Jones gave a very interesting address on the production of fine comb honey. His address was, in brief as follows: I do not want a colony too strong with bees. I prefer 6 or 7 frames only. Don't put the sections on too early; wait until white clover is fairly started; give starters only, in sections, placing the sections the same way as the frames. I recommend removing the sections early. I do not aim to secure the most honey, but the best looking and most salable.

N. Hutches.—Does it pay to feed back partly filled sections, to finish others with?

It was not considered profitable.

Pres. Root gave a detailed description of the Heddon hive, its management, and its good and bad features. There was considerable discussion on the same, the majority not favoring it.

Mrs. Culp expressed herself somewhat as follows: I do not think it profitable to change an apiary of 40 or 60 colonies for any new improvements in hives, discarding old ones.

To show what could be done with the old L. hives and fixtures, she gave an interesting account of her management of an apiary, how she handled an apiary of 40 colonies without help. She uses a modification of the L. hive, and keeps her queens' wings clipped. Her report for the past season was 5600 lbs. of comb honey, for which she received 18 cts. per lb.; 2400 lbs. of extracted, at 15 cts. Her bees are hybrids. She prefers them for honey to any others.

AFTERNOON SESSION.

After the convention was called to order, the subject of honey adulteration was opened for discussion.

Mrs. Nathan Hutches.—A young man of polished manners—a college graduate, as he said—informed me that he had seen, in the city of New York, comb honey manufactured; that he had seen them make the comb, fill it with the abominable stuff, and cap it over with thin wax by means of a "rocking concern."

President.—Didn't the fellow see them fastening foundation into wired frames with a foundation-faster?

Mr. Hutches.—No, sir. He appeared to be a straightforward sort of fellow. He said he had no object one way or the other in stating these facts. Mr. Earle Clickinger heard the same story.

When the latter gentleman, a honey commission-merchant, was called upon, he verified what the previous speaker had said. He stated that he believed that the young man who had given these facts was still in the city. Upon motion of the convention, Mr. Hutches was instructed to call upon the fellow at his place of business, bring him to the convention rooms, and let him tell his story. After a lapse of a short time, Mr. H. returned and reported to the convention that the college fellow had "gone west." The convention then instructed Mr. H., that, if he ever saw the polished young man again, to inform him of A. I. Root's offer of \$1000 to any one who should prove that comb honey could be manufactured.

C. E. Jones.—I think that comb honey is often taken for adulterated when it is made of honey-dew, or some kind not usually gathered.

After further discussing this matter, the following question was propounded: Does the queen determine the sex of her progeny at will?

Mr. Miller.—I have been taught, that the sex of

the bee is determined by compression, owing to the size of the cell.

C. E. Jones.—I think she has the free power of determining the sex.

Secretary.—I have seen the queen lay eggs in queen-cells only slightly started; also in foundation that was not drawn out more than $\frac{1}{8}$ of an inch. How does the compression theory account for this?

Mr. J. L. Mock gave a new use of wide frames for division-boards. Nail thin boards on each side, filling the space with dry sawdust, forest-leaves, or some light material. They are good for winter or summer use.

As many were desirous of getting off on the afternoon train, the convention proceeded to matters of business. It was moved and seconded that a committee of one be appointed to prepare a question-box for next meeting. The chair appointed S. R. Morris. The committee on exhibits reported as follows: Frank A. Eaton, section case and skeleton honey-board combined, adapted to the tiering-up system, and removing sections with ease. Mr. Earl Clickinger exhibited a section crate, a case of fine comb honey; jars of extracted honey; Bingham smoker and honey-knife and Eaton feeder. J. W. Newlove, combined shipping and honey crate; also well adapted for tiering up.

Bluffton, Ohio.

FRANK A. EATON, Sec.

HONEY EXHIBITS AT FAIRS.

THE ADVANTAGES OF ADVERTISING IT THAT WAY.

KNOWING that you like to see novel things in bee culture, I herewith send you a photo of my exhibit at our county fair. The boxes in front show for themselves what they are—honey-cakes and Todd's honey-candies, with an observatory hive on the left. On the right is a log cabin, made entirely of different styles of honey cans and pails, with sections of comb honey for windows and doors. The roof is covered with strips of foundation, and the appropriate name of "Home, Sweet Home," over the door.

The next structure bears upon the banner the title, "Beeswax Pavilion," after the Grecian models. This is a hexagonal framework of wood, covered entirely with foundation. The narrow spirals upon the columns are of colored wax, one column covered with green spiral, the next with red; the bands of foundation around the upper part were also of different colors, all surmounted with a flag-staff and a banner. In the center of the pavilion was a small pyramid of beeswax surmounted with a bouquet of wax flowers.

The next object is an exhibit of comb honey, in the form of a double arch, each section glassed. In the center was also a pile of comb honey. This double arch was finished out with a fine bouquet of natural flowers, scarcely discernible in the picture. On the left of the comb honey is a pyramid of extracted honey in tin and glass cans.

This exhibit attracted a great deal of attention, and called forth expressions of "Isn't it beautiful?" from scores, and I was kept quite busy answering questions, and giving information generally. This exhibit was shown at three county fairs—Warren, Saratoga, and Washington. At Ballston, Saratoga Co., we had a fine display. Mr. Tarent

HONEY-EXHIBIT AT THE FAIR, OF J. H. MARTIN, HARTFORD, N. Y.

was upon my right with four observatory hives, and a quantity of honey and implements. Mr. Smith was on my left, with three observatory hives, also honey, etc. Such displays, with the distribution of circulars and cards, and sale of honey, does much to instruct people.

I find, that if honey is sold cheap enough any quantity can be sold. A very nice package that goes off quite rapidly is a 5-lb. pail for 50 cts. Leaflets and cards are good things to distribute. I send herewith *The Facts*, that I am circulating.

My crop of honey this season is about 10,000 lbs. —7000 clover, 3000 dark. A good share of the clover, which is of excellent quality, will be disposed of in the home market, and earlier in the season than I ever sold before, and at much better prices than I can get when sending on commission.

Hartford, N. Y.

J. H. MARTIN.

The above makes a very beautiful exhibit, friend M.; but may I venture the suggestion, that there may be an extreme in going to more expense in time and money than is warrantable? Where one has a large crop of honey to sell, however, and deals in supplies largely, the advertisement it furnishes may make it a good investment, and perhaps your exhibit has been the means of selling your large crop of honey so early in the season. Your "Facts about Honey" are so good I should be glad to give place to them, did space permit. I think I may say to our readers, however, that you will be glad to mail them to any one on application.

THAT ESTIMATING COMMITTEE.

FIXING THE PRICE OF HONEY.

I DO not think that a honey-producers' association will ever be able to control the price of honey. It may be able to advance prices a cent or two, or prevent lower prices, in the large centers; but producers will ever be harrassed by low prices. A few years ago, when wire nails were introduced they were quite expensive, and the manufacturers made large profits. Competition was light. Soon other firms commenced making them, and better methods of manufacture were necessary. To-day large factories, with expensive and ingenious machinery, employing hundreds of men, with division of labor brought down to perfection, make them at a profit of a very small fraction of a cent a pound. Does any one think they will ever be made at a larger profit to the makers? Only a scarcity of iron can advance their price. So only a scarcity of nectar will appreciably advance the price of honey. Darwin's "survival of the fittest" comes in here. He who can produce honey the cheapest is the fittest. He who sells too cheaply will go down, as will he who produces at too much cost.

An estimating committee can only estimate the yield. I do not believe they can fix the price; however, they can estimate that too. But the bee-keeper, knowing the estimated yield, can "fix" the price of his own honey. However, let us have an estimating committee, composed of two or more of the largest honey-producers in each State of the Union, where honey is produced; and let us have some sort of an association for the purpose. J. H. LARRABEE.

Larrabee's Pt., Vt.

Very good, friend L. But there is another

thing to be done still, although the estimating committee may not be the ones to do it; and that is, to introduce the honey to everybody, and make them understand the very low price at which it is now offered to the consumer. The point you make, that he who sells too cheaply, as well as he who produces at too much cost, must fail amid the brisk competition that is coming, is worthy of consideration.

FROM 113 COLONIES, 13,000 LBS. OF HONEY, SPRING COUNT,

AN INTERESTING LETTER FROM OUR OLD FRIEND J. P. ISRAEL.

BEES have done tolerably well this season. I sold over 19,000 lbs. of comb honey, and had several cases of extracted. We had 113 colonies to start with in the spring. We wound up the season with 275 stands. If we get through the dry season with 225, and reach the black-sage bloom with that number, I shall be satisfied. My brother and I have dissolved, but I advised him not to move his half of the bees away until that bloom comes.

OIL FOR IGNITING FUEL IN SMOKERS.

I see you have a new kink, using oil for smokers. It is not new, by any means. I have used dry horse-manure and oil for 4½ years. I blew up my smoker the other day—too much oil. I have often had it jump and kick, but this time it fairly blew up—blew out of my hand, turned a summersault, and split wide open in the bottom.

THE SOLAR WAX-EXTRACTOR IN USE FOR 25 YEARS.

I see by the Oct. 15th No. that you say the credit of the invention of the solar wax-extractor belongs to O. O. Poppleton. I can prove that it has been used in San Diego and Sacramento Counties, this State, for 25 years. I can likewise prove that there is now, on the next farm below me, an extractor which has been in use on that farm for 15 years. It is made as complete and perfect as any of the present day. It is 10 feet long, 3 feet wide at top, and tapering to nothing at the bottom. These extractors are, and have been, used entirely for melting comb honey, and thus separating the honey and the wax. It was the only way they had to make "strained" honey. Many large apiarists have them 16 feet long, 4 to 6 feet wide, and covered with hinged sash, made on purpose for them. Only one thickness of glass is used.

The only way here to keep combs is to put them in the top stories of the hives; then you may calculate on losing from one-fourth to one-third of them. They dump these combs, frames and all, into the solar extractor. The next morning (or that evening) they can take out their frames, perfectly clean. For these two purposes the solar wax-extractor has been used in California for many years. I used it for another purpose, and tried to say so, but you did not appear to see the point. I take a large flat pan and fill it with the wax thus obtained, or even old dirty comb. Set it high up next to the glass. Put in a pan, the shape you want your wax for market; have a spout in the upper pan; let it drip into the lower one. There your wax is, ready for market. J. P. ISRAEL.

Encinitos, San Diego Co., Cal., Dec. 14, 1886.

ADVERTISING WHAT YOU HAVE FOR SALE.

DOES IT PAY? AND SOME GENERAL HINTS TO ADVERTISERS.

IN the office, I believe it is generally considered that the advertising clerk has one of the most difficult and responsible places of any of the girls in that room. It seems that, in spite of any precaution we have been enabled to take, there is almost continually some degree of dissatisfaction. The most comes, however, from taking out an advertisement, or from leaving it out, when our customer wanted it in. In view of this I have told the clerk to be sure to have the mistake come by getting in an advertisement when it was not wanted, rather than to leave it out when it was wanted. Advertisers, like many other people, are sometimes in a great hurry, and they hurry off the notice at the last moment, as it were, omitting or forgetting to say how many times the notice is to be inserted, the length of space they wish to have it cover, and frequently do not say whether they want it in every issue, or only the issues of the first of the month. Let us take an illustration, for instance. The following is the contents of a postal card:

Please put under the department, "Queens for sale," we have for sale 6 very good tested Italian queens, 1 Hybrid, at \$1.00 each, or \$6.00 for the 7. Hybrids, 35c. Send \$1.02 to return your money if queens are sold before your order comes.

MODEL BEE-HIVE CO.

W. Phil'a., Pa., Aug. 23, 1886.

You will notice in the above, that our friend does not say a word about what issue he wishes it to appear in, nor does he say how many times. Under the circumstances, on receipt of such an order the advertising clerk sends back by first mail a printed letter which reads as follows:

Friend,

Your favor ofinclosing \$.....received with an advertisement, which we will insert in numbers, as you request, or until otherwise ordered. As you do not mention the amount of space, or the number of lines you wish it to occupy, or give any instruction as to display lines, we will set it up so as to make such an appearance as we think it ought to present. We will send bills after each insertion, for the space occupied. If the above is not satisfactory, please reply by return mail, on inclosed card, giving us correct instructions. According to our advertising rates, given below, we will credit you with the discount at the expiration of the time you wish it to run.

Yours respectfully, A. I. ROOT, Per.....

You will notice, that, in with this printed letter, we inclose a postal card directed to ourselves, so that our customer may take a pencil out of his pocket and tell us what to do, even while he stands in the postoffice, if he chooses. We prefer to pay for these postal cards, and to pay the postage on the letter we send them in, so that our bee-friends may have no excuse for failing to inform us immediately, if our proposal is not satisfactory. We do this, because it is so very difficult a matter to get people to write and tell

us what they do want. Now, after we have done this, our advertising clerk has instructions to insert the advertisement until we get some kind of notice from the advertiser, saying that he does not wish it continued any longer. It seems to me, that almost any sensible man will say, if there is any thing *wrong* it certainly is not *our* fault. A good many troubles have come up, notwithstanding these precautions. Quite a number of pretty good men—that is, we have always considered them to be such—have refused to pay their advertising bills, giving, as a reason, that they ordered the advertisement stopped. Now, after we have very kindly explained to them that their letter ordering it stopped did not reach us until the journal had gone to press, they still object. In one or two cases where advertisements have been ordered out, the order was written within three days of the last of the month; and yet the advertiser claimed he was under no obligation to pay.

Now, in regard to the postal card we have given above. The advertising clerk inserted the advertisement four times, at a cost of a dollar each insertion, before we got a word from the Model Bee-hive Co. Then he claimed it was ordered in for only *one* insertion, in the first place. He writes in regard to it as follows:

We wrote to you, saying to put said advt. in Sept. No. of GLEANINGS. We left home shortly after the first of Sept., and just returned home last night, and, to our surprise, you had continued said advt. (on examining GLEANINGS), and sent two or three postals, stating amount due you. We wanted said advt. only in Sept. No. If we had wanted it in any other numbers we would have told you so.

MODEL BEE-HIVE CO.

West Phil'a., Pa., Oct. 27, 1886.

As we have published every letter and figure on his order, one can readily see that our friend is greatly mistaken; and the advertising clerk and book-keeper, without bringing the matter to me, wrote him that they could return his order if he wished, to show him that he didn't say a word about putting it in the *September* issue; therefore that we should expect him to pay for his neglect in not notifying us. On my return from the Albany Convention, the card below was handed me, which was sent us, I presume, in answer to a statement in regard to the remaining \$3.00.

We wrote you some time ago, Oct. 27, thinking that you were charging us for running our advt. which we did not order. If you will look up our letter, which will tell you all about it, we do not care to repeat it here. However, of all the advertising we ever did in GLEANINGS, it never paid us $\frac{1}{2}$ of our advertising money back. Make a note of this, and publish it in GLEANINGS, as you never say any thing about those that write you about advertising not paying—only those that say that their advts. paid. Come out with both sides of it, and oblige

Respectfully, MODEL BEE-HIVE CO.

West Phil'a., Pa., Jan. 14, 1887.

I read it over in a little surprise, and asked for the whole of the correspondence in the matter. Now, the advertising clerk, the book-keeper, and, in fact, almost everybody, would say that our friends of the Model Bee-

hive Co. are *entirely* at fault. If they permitted the advertisement to run through neglect, or even through absence from home, there was no one at fault at all except themselves, therefore they should pay the bill. Very likely the above course would be *justice*; but you know, dear friends, I have been talking to you a good deal, not only for months, but even years back, in regard to doing a little *more* than justice by our fellow-men. "If a man compel thee to go with him a mile, go with him twain." I read a little more carefully the letter of protest made by our friend when he received a bill for \$4.00 for advertising, and in it I found the following:

The queens were offered for \$6.00, and you send bill in for \$4.00! Not much profit. Besides, the queens remain unsold. I did not get one offer; we did certainly not expect to advertise them to their full value, or else we might as well have sold you the queens for two dollars. Besides, it looks bad to advertise 6 queens 4 times. It does not look as if we were selling queens fast. I think common sense or judgment would have told you, or any one else, that we could not offer queens so low, and then spending all the amount for advertising them, to sell them.

MODEL BEE-HIVE CO.

West Phil'a., Pa., Oct. 27, 1886.

Now, there may be differences of opinion here. A good many will say, "Although it does look very bad to pay out \$4.00 for advertising \$6.00 worth of queens, it was entirely the fault of the advertiser for not saying how many times he wished the advertisement put in." It was mainly his fault, I agree; but I think, dear friends, he is right in saying that common sense or ordinary good judgment ought to have decided that no man in his senses would wish to pay \$4.00 for the *chance* of selling \$6.00 worth of goods. Who is at fault, then? The editor of GLEANINGS? You may say, "The editor of GLEANINGS, with his multitude of cares, can not go into every little matter like this, without breaking himself down, mentally and physically." The advertising clerk is also burdened with so many cares and so much business that it is pretty hard for her to stop to inquire whether a man knows what he is talking about or not, when he sends in an advertisement. To avoid similar cases I have asked Ernest to examine every advertisement, and be sure that it makes good sense before it is allowed to go into print, and I think he has done his work pretty faithfully. In reviewing the above advertisement of late, he would say at once that it was all straight and consistent. If somebody had asked him, however, if it was probable that this man wished such an advertisement *continued*, he would at once have decided not; but he is already pretty severely burdened with a multitude of cares in his work on GLEANINGS. The proof-reader made sure it read according to *copy*, and that ended *his* part of it.

Let us now consider the latter half of communication No. 3. He says, in substance, that the advertisements he has put in GLEANINGS never brought him a *third* of the money he paid to have them *inserted*. This is a pretty bad showing for GLEANINGS, dear friends. I am well aware, that a good many

advertisements do not pay the friends who send them. Quite a number have refused to pay for advertising, on the ground that it did not do them any good, and I have been asked to excuse them from paying an advertising bill because the advertisement profited them nothing. I have refused to excuse, on the ground that it was no fault of mine. *Sometimes*, it is true, I am asked if I think a certain advertisement will pay; and I remember that I have, a good many times, replied back that I felt pretty sure that it *would not pay*. Yes, I have sometimes written to friends who wanted certain things advertised, that I felt sure it would not pay, even *before* my opinion was asked. I have been pretty roundly abused once or twice for making similar suggestions. Knowing the supply of queens there was in the market in September, I could have told the Model Beehive Co. beforehand, that their advertisement would *probably* do them no good—had my opinion been asked. Now the question begins to assume something of this shape—"Am I my brother's keeper?" To which I reply, "Yes, sir. *I, for one, am my brother's keeper.*" I want God to hold me responsible, not only for my brother's spiritual welfare, but for his financial welfare; and my decision is, that, under the circumstances, we ought not to ask pay for the three last insertions. If my mental strength does not permit me to take a brotherly review of all the advertisements sent in to us, it is my business to employ somebody who can intelligently advise our bee-friends in regard to inserting advertisements. And the moral to this whole long story is, to ask you all,* in sending in advertisements, *if you feel inclined*, to ask our opinion in regard to the advisability of inserting said advertisement. We will advise the best we know how, and without charge. This advice, I presume, will cut down part of our advertising patronage, but I shall be glad to cut it down, because I know that a goodly part of it has not been profitable to our hard-working and close-scraping bee-friends, many of them. After having given this advice, you are to act as you see proper, and we can not be responsible for the profitableness of the transaction any further.

TEASELS, AGAIN.

SOME GOOD ONES FROM THE PACIFIC COAST.

SINCE the appearance of a series of articles on the teasel-plant and its culture in one of our local papers, and two or three short articles in GLEANINGS from which extracts were made by the N. Y. Tribune and other leading papers, it has been ascertained that teasels of good quality are grown in Oregon. That fact alone has set our dealers at work, and the result is, that several carloads have already been shipped here and held at our railroad station for inspection and re-shipment to factories. That they are of good size and good quality, there is no mistake; and, for

*Of course, the *veterans* in advertising, who have had sufficient experience to know whether it is important for them to advertise or not, and how much, would hardly care for my opinion in the matter.

ought I could see, are *fully* equal to our own growing. I intend, when I write on any subject, to be accurate, and keep myself posted; but it was this very writing that unearthed the existence of that French colony away out on the Pacific coast, quietly growing their teasels and supplying their neighboring mills. If the quality is good in Oregon and here, I believe there are *many* other places, when found, that will prove to be adapted to the growing of this crop. I had also supposed that the expense of shipping and then reshipping would be too great to warrant any one in raising them if they were far from a market. What I mean by a market is a middle-man, or dealer.

Now, you will ask me why the grower can not ship direct to the factories. We will suppose that the first factory that saw fit to order of you made a specialty of woolen blankets. Of course, for that coarse work they would want "kings," and you would not have enough in your whole crop, of the right size to fill their first order; and your next sale would be as likely to be kings as any thing. Without carrying this comparison further, you can see that, in order to deal direct, one must carry a stock of a good many thousand dollars' worth; and, further, the handling, sorting, and packing, is a trade of itself. But if our dealers at present prices (6 cts. per lb.) can pay freight from Oregon, and then compete with us, I think some of my good bee-friends had better look into the matter.

I will answer any question through GLEANINGS that its editor may see fit to ask, but I can not undertake to answer by private letter.

Thorn Hill, Onon. Co., N. Y. C. M. GOODSPEED.

THE NON-USE OF FOUNDATION.

A REPORT FROM W. Z. HUTCHINSON'S OWN NEIGHBORHOOD.

AFTER reading the articles on the non-use of foundation which have appeared from time to time in the bee-papers, I think the "other side" should have the benefit of the following:

Mr. W. Z. Hutchinson has a neighbor, Mr. C. D. Doane, living about two miles distant. In the spring of 1886, Mr. Doane purchased 350 of Mr. Hutchinson's discarded combs. That season Mr. Doane produced 6500 lbs. of honey from 50 colonies, spring count—an average of 130 lbs. per colony. If I am not mistaken, Mr. Hutchinson had 8700 lbs. of honey from 55 colonies, spring count—an average of 121 9-11 pounds per colony. At the close of the season, Mr. Doane's bees had an average amount of 30 lbs. of honey—natural stores—to winter upon, while Mr. Hutchinson's bees had to be fed sugar syrup. Mr. Doane attributes his larger honey product to the combs purchased from Mr. Hutchinson. Mr. Doane's bees increased to 125 colonies. Mr. Hutchinson's increase I do not know. I think the amount of increase would be likely to affect the general result somewhat.

I have Mr. Doane's figures from that gentleman himself, but am not so fortunate with those of Mr. Hutchinson, but I think them correct.

Flint, Mich., Jan. 17, 1887.

M. S. WEST.

We are very much obliged indeed, friend W., for your communication, for it proves this, if nothing more: That friend Hutchinson has an exceedingly good locality—or, at

least, it has proved so during the season that is past. If Mr. Doane increased 50 colonies to 125, and secured over 130 lbs. per colony, he certainly did exceedingly well.

PEDDLING HONEY.

FRIEND COLTON RELATES HIS EXPERIENCE.

IT is very pleasant and agreeable to me to read the reports of those who have been successful in marketing their honey. I have not yet read a report of a failure in peddling honey. This strikes me as somewhat remarkable, as my experience has been quite different from that of those who have reported their success in GLEANINGS. Evidently, those who found peddling honey a poor business thought their report would not tend to the "encouragement of bee culture." There is a short time after our busiest time with the bees is over, and before cold weather has caught us, that we can profitably market honey as peddlers. We can then draw it off from a barrel without the necessity of charging our customers for a tin pail or jar, which, when added to a small purchase, raises the price above the price of comb honey. If you peddle near home you can call for your pails after the honey is used; but peddling near home will not suit the groccerymen who are selling your honey.

A bee-keeper from a town near me told me he had disposed of about 7000 lbs. of extracted honey by peddling it out at 9 and even 8 cts. per pound. He had canvassed, I think he said, nearly every town within one hundred miles of home. In many towns, bee-keepers are trying to keep the price of honey up to something above the cost of production; and when the honey-peddler strikes a town where he can undersell those engaged in the production of honey, his sales are apt to be quite satisfactory. Somehow I can't get very happy and enthusiastic over the honey-peddling scheme. Few bee-keepers will make themselves so notoriously honest, and their honey so perfect, as to be above suspicion for any great distance from home. Brother Root, we do not all have the faculty and experience in advertising that you have, even if we controlled a publication like GLEANINGS, which circulates to a certain extent through all our States and Territories. I rigged out a wagon for peddling, and spent about a week at the business. I averaged a sale of about fifty pounds per day. When I could not sell a pail, I dug out, of a large can, granulated honey, but, of course, found this tedious, as cold weather was gradually setting in. I intend to rig up a sleigh of some kind and continue the fight, even if it takes all winter, and I have no doubt it will. There is no other way left for me to dispose of my crop of honey. I tried, in the latter part of last winter, to get something out of what honey I could not sell at home, by sending it to St. Louis, to be sold by a commission merchant. I realized for the honey, after deducting cost of pails, freight, and all charges, a trifle over two cents per pound. Said honey was well-ripened clover and basswood, but a portion was produced the year before, and kept over, as I could not get rid of it. I got honey in all of the stores near home I could, and they offered it at ten cents per pound. I hope you will publish this, and some one who has had more experience than myself in peddling honey

will show where I have erred in my conclusions on this plan of peddling honey. The point is, can we increase the consumption of honey more by peddling than by leaving it at the groceries? I do not wish the mistake made, that, because we get a fair sale by peddling honey at a price lower than our brother bee-keepers who are already selling low enough, that this policy will be wise in the long run. Our rivals in the business will be compelled to come down also; and when the price gets so low that you can not undersell, peddling will fail to relieve us of the problem of disposing of our honey.

J. B. COLTON.

Waverly, Ia.

WILL HONEY EVER BECOME A STAPLE?

SHALL WE ORGANIZE TO KEEP UP PRICES?

I HAVE disposed of much the largest share of my fifth and largest crop of honey; and although I have not been in the business nearly so long as Heddon or Dadant, I have nevertheless followed it long enough, and at just the right time, to suffer from the most sweeping decline in prices that any natural product has perhaps ever known.

The year 1882 was a good one in this locality, and honey wholesaled at 20 and 25 cts. per lb. I do not like to tell what I have obtained for the bulk of my comb honey this year. Every year since the first one, I have been laboring to develop a market at and near home, and I think I have obtained a pretty fair idea how nearly honey is likely to become a great staple. I am certain of two things; viz., that honey will never become a universal staple, and that lower prices do greatly increase consumption. I can give items of experience which go far to demonstrate these propositions. It is a matter of continual surprise and wonder to me that the majority of folks do not like honey. Not one out of ten whom I tackle on the subject cares anything for it. I eat over half the honey used in our house; and I find among many of my best customers, that about one of the family is all who takes it. I have pretty much learned whom it is worth while to approach around home.

Springfield takes the largest share of my honey.

I tried an experiment this year, which has taught me much of the lesson I have been steadily learning for four years. With a large crop, overstocked markets, and low prices; with more honey than money, I resolved to try how near I could make the former take the place of the latter. I had some building to do, and I canvassed the city with a view to trading honey for materials, so far as I could. I would patronize him who would patronize me. I found just one lumber-dealer in the place who would trade that way. He would have—how much do you suppose? *Three pounds!* After visiting half a dozen paint-shops I found one man who would do somewhat better. He ordered enough to pay for paints and brush. I canvassed the hardware-stores, without avail. Dry-goods stores and shoe-stores were tried unsuccessfully. I sold 10½ lbs. to one hatter. Almost the unvarying note was, "We do not like honey." It looks like small business at the start, and it turned out so small that I shall not work very much in that line.

As I had a few apples and potatoes to sell, I re-

solved to try the women at their homes. I had had some experience in selling fruit and vegetables some years before, and I had learned that that was the way to make trucking profitable. Women like to have living necessities brought to their doors. There were fruit and vegetable wagons on every street, while I, almost alone, offered honey. Yet I could make six sales of either one of the other products to one of honey. They never interfered with a honey sale either. In the light of my experience, how Mr. France succeeds so well in peddling honey is a riddle to me. Yet I say, that lower prices will greatly increase consumption. The volume of business has vastly grown around here, and I believe it will continue to grow. That this growth is largely due to the fact that the business has been worked up, is no doubt true; but I know very well that a great deal that has been sold this year would have remained unsold at higher prices. For example, Mr. W. sells comb honey at 12½ to 15 cents, and a number of customers, somewhat like one he mentioned, a day laborer, buy considerable at the former price, who purchased but little when it cost more. In 1882 Mr. W. sold about 100 lbs. for me at 22 to 25 cts. In 1883 the price fell to 15 cts., and he sold about 250 lbs. The next two years the crop was short, with prices higher and sales less. In 1885 he retailed at 18 cts., and sold perhaps 250 lbs. for me. This year he has sold lower than ever before; and what is the result? He has already disposed of over 400 lbs., about 120 lbs. being extracted, and I am to deliver him about 150 lbs. of the two kinds this week.

Said Mr. W. to me, "I can see that it cuts into the syrup trade like every thing."

You see, at such prices honey becomes a competitor with other commodities. Four years ago, only a few of the principal stores offered honey for sale; but now the stock in trade of none but a few suburban grocers is complete without it.

Prices will not continue to decline as they have been doing. We shall reach rock-bottom pretty soon. I am very willing that honey should be put within the reach of the poorest. We owe this to humanity. A honey-pool is a chimera. One hundred manufacturers of an article may combine and control the market; but tens of thousands of hog-raisers or honey-producers can not. But if they could, I do not want them to do so. I am opposed to great or petty monopolies, as all such combinations tend to become. We should, instead of trying to keep up the price of honey, do our best to make our industry profitable by producing at the lowest possible cost. GEO. F. ROBBINS, 93-61.

Mechanicsburg, Ill., Jan. 10, 1887.

FEEDERS.

HOW TO MAKE THEM.

"IN times of peace prepare for war," is an old saying. While I hope we in this country may never be called upon to prepare for another war with swords and musketry, yet there is always in this life a need of a warfare, and a preparation for the same, if we would be successful in the undertakings of life; and as in battle the army is most likely to be successful which has been thoroughly prepared in "times of peace," so the person who uses his leisure hours in getting prepared for the "heat and burden" of the

harvest time is the one most sure of success. In nothing is this more true than in bee-keeping; and yet the majority of bee-keepers while away the winter days and months, not seeming to think that another season of heat and toil is coming until the season is upon them. To the truth of this, nearly every supply-dealer can testify; for in spite of discounts offered, and entreaties published and otherwise made during winter, all know that the great rush comes in May, June, and July. These thoughts were brought up by a friend desiring to know how I made my bee-feeders, and saying, "I want to get every thing in readiness this winter for another summer." I predict for that young man a successful life, health and strength being given him. As I have just finished making a lot of feeders I thought it might not be amiss to answer his question through GLEANINGS; for after trying nearly all the feeders ever advertised, I like the best of any the one about to be described, so I have discarded all the others. The idea of such a feeder I got out of some of the bee-papers; but when and where, I do not know. This feeder I call a division-board feeder, yet it is different from any such feeder which I have ever seen described.

To make, get out one piece $\frac{3}{4}$ of an inch square, and the same length as the bottom-bar to your frame, providing the end-pieces to your frame are nailed to the end of the bottom-bar. Otherwise make this piece as much shorter as the two end-pieces of your frame are thick; for it is to hang in the hive the same as any frame. Also the end-bars and top-bar are to be only $\frac{1}{4}$ inch wide, as a feeder of that width keeps the bees from drowning without a float, while, if wider, a float is necessary. Besides these four pieces spoken of above, you want two very thin boards (I make them 3-32 of an inch thick), the same size as the outside dimensions of your frame, less $\frac{3}{4}$ of an inch at the top, it being supposable that the top-bar to your frame is only $\frac{1}{4}$ inch thick. In any event there is to be a $\frac{1}{2}$ -inch space between the under side of the top-bar and the upper edge of the thin boards, for an entrance to the feeder.

Next, get some white lead and thin it with boiled linseed oil till of the consistency of thin cream; for all the joints of the feeder are to be fixed so there can be no possibility of leaking. Now with a small marking-brush put some of the thick paint on the end of the $\frac{3}{4}$ bottom-bar, and also on the lower end of the end-bar, where it is to be nailed to the bottom-bar, and nail together, preparing the other side the same. Next lay down your frame, which is complete, except the top-bar, and paint the sides which are up, and also around the edges of three sides of the under side of the thin board where they are to come in contact with the frame. Place the board so it comes even with the bottom and outside of the frame, and nail on, using $\frac{3}{4}$ -inch wire nails, and driving the nails from $\frac{1}{2}$ to $\frac{3}{4}$ inch apart, when the other side is to be treated the same way. Now take the end-bar of a frame and saw it off short enough so it will come up within $\frac{1}{4}$ of an inch of the top of the inside of the feeder, when it is to have three $\frac{3}{4}$ holes bored in it near the bottom, the bottom one cutting out just a little at the end. Slip this down in the center of the feeder, and nail each side to it. This piece is to keep the thin sides of the feeder from bulging out when the feeder is filled, and the holes in the bottom of the stick are to allow the feed to run through from one side to the other, or it will be filled only from one side.

There is nothing more to be done with it at present, except to paint the outside with two good coats of paint, when it is to be set away for two or three months, to have the paint thoroughly dry in the joints. When thus dry, melt five or six pounds of beeswax or paraffine (the latter preferred), heating it quite hot, and pour into the feeder till full, when it is to be poured out again in a moment or two, using it for another feeder, and so on till all are coated with wax on the inside. If the wax is quite hot and the feeder well warmed, it will penetrate the wood to the depth of 1-16 of an inch, which is a double preventive against leaking, while the main object is the keeping of the wood from taking up the feed by soaking, in which case the feeder soon becomes sour, and will sour the feed ever afterward, unless at once taken up by the bees.

We are now ready for the top-bar, which, after having a hole bored in it near one end for the point of a funnel to enter, is nailed on. Our feeder is now complete; and, barring accidents, it will last a lifetime.

HOW TO USE.

To use it, hang it in the hive the same as a frame; and if the colony is at all weak, put it at the side of the hive the furthest from the entrance. In fact, I always use it at one side of the hive; for in that case the slit which is cut in the quilt over the hole through which the funnel is inserted is always in the right place, while otherwise it would not be. Having the feeder in place, and the slit cut in the quilt, insert the funnel, pour in the feed and remove the funnel, when the slit will close up so no bees can get out or in the way. Twenty cubic inches of ordinary honey will weigh one pound, so it is easy to tell how many pounds your feeder will hold. Mine, made to fit the Gallup frame, holds nearly 5 lbs., so I am sure not to run it over, if I feed $4\frac{1}{4}$ lbs. at a time. If I wish to feed more at a time I use two or more feeders; if less—well, I will tell you just how I do, even if it does make this article a little long.

To carry feed, I use a common watering-pot with the rose, or sprinkler, taken off. This watering-pot is set on the scales, and feed poured in till one pound is registered. I now, with the point of my knife, scratch the tin a little at the top of the feed in three different places, about equal distances apart; pour in another pound and mark again, and so on till the vessel is as full as I can carry it, which is generally about 15 lbs. I now pour out the feed, and wash and dry the watering-pot, when I touch a little paint, made of red lead, on each of the places scratched with the knife, and by the side of them I place figures, made with the same paint, from 1 up to 15. When this paint becomes dry I always have a scale of pounds with me which tells me at once how much feed I have, and just what I am doing, as soon as I hold the watering-pot level, and glance down into it.

Now just a word as to why I like these feeders. Placed where I put them, they become a part of the side of the hive; and by knowing that the cluster of bees is next to them (as a few minutes' preparation will always make them), they will take the feed at any time of year if the feed is a little more than blood-warm when fed, so there is no danger of feed not being taken in cool or cold weather. Second. These feeders require no storage room, as they can be left in the hive when not in use, if it is wished so to do; and at such times they can be used as a division-board. Third. The weakest nucleus can be fed with no danger of robbing, when used as I

have directed. Fourth. They are always handy, and no bees are in the way to bother while filling. Fifth. No float is required, as is the case with many of the feeders. Reader, make one or two for trial, during your leisure hours, and see if you do not agree with all I say.

G. M. DOOLITTLE.

Borodino, N. Y., Jan., 1887.

Friend D., you have given us some important suggestions in regard to the use of what has been called a division-board feeder; but why not cut into a solid piece of board with a circular saw, instead of having so much trouble to nail it up, and wax and paint it? The solid piece of board would probably hardly hold five pounds of honey; but it seems to me it would be much cheaper and more substantial. There are two or three patterns in our museum that have been sent in at different times. One great objection to these feeders with us was the running-over while filling; but this matter you have very ingeniously remedied.

HOW LONG HAS EXTRACTED HONEY BEEN ON THE MARKET?

FRIEND DADANT'S COMMENTS IN REGARD TO THE STATEMENTS ON PAGE 21, JAN. 1.

FRIEND Heddon, are you not making yourself older than you really are? Did you say 28 years since we have been producing extracted honey? and "during all this time friend D. and his class . . . etc."? I am trying to believe that it is a typographical error, and that you meant 18 years. But even *that* won't do, as I will show.

Friend Heddon, you have a historical record in the old *A. B. J.* that you ought to refer to once in a while. Let me give a few reminiscences:

In 1865, 22 years ago, the honey-extractor was invented.

In 1868 it was first described in the *A. B. J.*, Vol. 3, page 189.

In 1870, *A. B. J.*, Vol. 6, page 118, friend Heddon reported 523 lbs. of *box honey* from 6 colonies, and stated that he had as yet no "emptying machine." So it is just *sixteen years*, not 28, since Heddon has been using the "extractor," and producing and introducing extracted honey.

But Mr. Heddon did as we did, and as you did, Mr. Editor; he began by extracting unripe honey. Then came adulteration, which we fought together for 6 or 8 years. Now, adulteration is about scared off, both by our denouncing and by low prices. The principal adulterators even went so far as to publish circulars to announce that they had stopped the practice. But honey has been *very* plentiful for only about three years; and, as I said before, it is *not even now* as cheap at retail as the wholesale prices would justify. In sugar- and syrups, there is but a fraction of a cent between the wholesale and the retail price.

Friend H. talks about "all this introducing!" Indeed, a little progress has been made. It took about ten years for us to obtain of the Boards of Trade the special quotation of "extracted" honey, which was going, and is still going, in many places, as "strained" honey. Why tell us that extracted honey will never be a staple, when its introduction is so new that not one person in a hundred knows the difference between strained and extracted?

The people who like honey better than syrup "*only because it costs more*," are the same ones who want strawberries in January and fresh oysters in July. Luckily we do not rely on this class for the sale of our extracted honey, for they will buy only the whitest comb honey, even if it is *horsemint* honey, taste being no object.

Friend Heddon says that the specialist alone will continue bee-keeping, and the small ones will drop out in the near future. Does not this prospect scare you, friend Root? More than two-thirds of your readers are either farmers, doctors, clergymen, etc., not specialists, and you are going to lose them! In answer, let me cite the words of Mr. G. H. Beard, a well-to-do farmer of Winchester, Mo., a bee-keeper, *not specialist*:

"I find more difficulty in selling honey than in raising it, or wintering my bees; but with all that, it is my honey that pays the expenses of my farm in these hard times."

To sum up: Honey is good, better than syrups. It can be produced as cheaply as cheap syrups, and must become a staple, sooner or later. We are too eager, too anxious, when we expect a radical change to take place in so short a time as that which has elapsed since we have found that we could produce it largely. Let us not become discouraged; let us sell *low*, and *around home*, and create a market for coming years.

C. P. DADANT.

Hamilton, Ill.

Perhaps, friend D., I should beg pardon for not having noticed the part referring to 28 years. I recall to mind now, thinking it could not be so long a time, but I did not know where to find the figures readily. I believe I produced the first ton of extracted honey put upon the American market. Mr. Langstroth had made a rude extractor, and tested the sale of the new liquid honey by putting several jars full on the market. I believe a record of all this was given in the *A. B. J.*, although I have not taken the time to look it up. If I have made no mistake, the honey-extractor was described in a bee-journal started in New York just a little before the *A. B. J.* resumed—somewhere about 20 years ago. The matter is of no practical moment, only it may be interesting to know just how long we have been teaching the people to use liquid honey, and I think friend Dadant's closing paragraph is pretty near the truth.

HONEY FROM THE WILLOWS, ETC.

HONEY-DEW ON THE BANKS OF THE MISSOURI.

IT may be interesting to you to know what the bees are doing on the banks of the Missouri at Bluffton, Mo. We commenced with 6 colonies, two of which were in Simplicity hives, the other four being in box hives. They commenced gathering pollen from the willows. The latter cover the islands here in the Missouri River, and are about the first thing to bloom here. On this they built up quite rapidly, and by the time fruit bloomed they were quite strong, when we transferred those in the box hive into Simplicities. It was our first attempt; but by following instructions in the *A B C* of Bee Culture we got through with it pretty well.

Bees commenced swarming earlier than usual, and did not seem to know when to quit. One could

see a swarm passing over almost any day; however, we did not lose any that we know of, neither did we allow ours to swarm more than once.

The white-clover and basswood yield was rather short. Basswood yielded honey only a few days. All the white honey we secured was about 100 lbs.

About the 28th of June we had one of the heaviest rains seen here for years; and after that we had none to amount to any thing for two months. This cut our honey-flow from flowers very short, as it set in very hot and dry just after the rain; but, fortunately, the honey-dew came in abundance, and the bees lost no time in taking advantage of the situation. They would be out at daylight, and from that until about 10 o'clock they seemed almost wild; but during the warm part of the day they would take a rest. This, we suppose, was due to the honey-dew being too thick when the water had evaporated. As nearly as we can estimate we extracted about 450 lbs., and procured about 25 lbs. in 1-lb. sections. We do not know exactly how much we extracted, as we have supplied father's house with honey since our first extracting; and being a family of seven, all of whom like honey, you may know that no small amount was consumed. Neither can we estimate just what it net us per pound, as we have not yet received returns for the greater part of it, but think it will be about 6 cts. per lb. We increased from 6 to 12, and bought three colonies from our brother, who promises to stay out of the bee-business in the future, so we count 15 colonies in Simplicity hives, not in the very best condition for winter, but trust they will come through all right, as they are sheltered from the northwesterly by a bluff—something which we consider a great advantage to an apiary.

We almost forgot to mention, that our own bees gathered some honey from a tall white flower that grows along the roadside, the name of which we do not know. We consider it equal to any honey we ever tasted. It is of a golden color.

If a hive is opened while the bees are gathering this honey, one can detect the scent of this flower at some distance from the hive. It is a very common weed here, but we consider it a splendid thing for bee-keepers, as it commences flowering in the latter part of August, and continues until frost.

MILLER BROS.

Bluffton, Montgomery Co., Mo., Dec. 31, 1886.

HOW OUR FATHERS DID.

HOW TO SECURE WORKER COMB WITHOUT FOUNDATION.

ACCORDING to the conclusions of several writers who tried to get perfect worker comb without the use of full sheets of foundation, as practiced by Mr. Hutchinson, it would seem as if there had never been any good set of combs before we had foundation. I wonder whether they have never noticed good combs among a lot of box hives to transfer. Wherever such are found it can safely be said that they are built by after-swarms. There may not be many so found, but more regular results can be obtained; and a review of old-time bee-keeping will make it more plain. As stated before, we then kept our bees in straw hives, cone-shaped, and others consisting of rings piled up with flat covers, all wide enough to hold 8 to 9 combs. We put a piece of guide-comb

in the center, and made them build straight. As the hives were all round, it will be seen that the center combs were the longest, and the extreme sides about the size of a hand. In order to get good stocks, with all worker cells, we put in early strong second swarms, natural or driven, and I do not remember of failing to get all worker comb, with the exception that one or at times both of these small side combs were built drone comb, simply enough needed by every colony. I say needed, because, if no drone comb be allowed them they will disfigure other combs or go into the sections for that purpose. In first swarms we expected more drone comb, especially where the queen was older than one year. It may therefore be best to give the latter foundation where new combs have to be built. I used to trim down the lower edges of too tough old comb, after swarming, which would be renewed, as soon as the young queen would be pressed for room, with worker comb. If such was practiced before swarming, more or less drone comb would be the result, and that for immediate use. Ever since I have used frames I do the same as I did in straw hives to get worker comb. I put strong swarms with young queens on 7 to 9 frames, 12 x 10½, and seldom see more drone comb than a little on one side. I so treated several last season, some of which are in L. frames. In the latter it is much harder to get full frames, on account of their large size and shape. It is necessary that such swarms be put in early, so that they fill the frames thoroughly; for if left for the next season they are almost sure to be finished with drone comb, unless the hive be inverted to have them finished above, and then there might be some, if they are in need of it.

To what extent foundation can be used profitably depends much on circumstances: what it costs one, whether he makes it himself, what his time is worth, etc. Foundation pays in all cases where no good results can be obtained without it, as in filling out the spaces in transferred colonies, building up of nuclei, late swarms, and adding frames, in increasing generally, where it is hard to get perfect worker combs built. As to moving surplus-cases with new swarms, I have also always practiced it; and as I work mainly for box honey I find it the best way to get even with bees that persist in swarming. It was also Mr. H. who remarked, some time ago, that as much comb as extracted honey could be obtained. Among the few believers in this I am one.

C. H. LUTTGENS.

Hammon, N. J., Jan. 9, 1887.

WARMING OUR HOMES.

FRIEND TERRY GIVES US A LITTLE TALK ON THE SUBJECT.

FRRIEND ROOT:—Some weeks ago I received two letters, thanking me for some things said in GLEANINGS, and asking me to tell how we warm our home. I am always glad to get and answer such letters, for then I know I am writing something that some one wants to know about. Like every other family, I presume, wife and I have our particular notions. For example, we do not like a furnace. Having been brought up around wood fires in stoves and fireplaces, we do not feel quite warm and all right, some way, unless we can see the fire. Then, again, a furnace

would make our cellar too warm to keep vegetables nicely. We want to keep the temperature there at about 34° during the winter. At that temperature apples do not rot nor potatoes shrink and sprout. Therefore we decided against a furnace. Then came the question, "Shall we have grates?" They are very pleasant and cheerful, and ventilate the rooms well, but they burn a large amount of fuel. In other words, a large part of the heat goes to waste. Then they are expensive, and it is a good deal of work to take care of them, and, really, in cold weather one wants to have the house warmed in some other way, when he has a grate to sit by. About the time we were thinking over this question of how to warm our house, after it was built, a gentleman who had just put in a grate, and was loud in its praise, asked me to go home with him one evening and see for myself how cheerful and comfortable it was. I went, and there sat the wife with a heavy shawl around her shoulders, and her feet to the grate. One glance told the story—comfort on one side. Well, wife and I, full partners, as Prof. Cook says, determined to warm our home so it would be comfortable, cheerful, and healthful, having due regard for economy and cleanliness, and so it should be as little trouble as possible to take care of the fire. For the latter purpose we determined that one large stove should warm the three main rooms below, and that it should be a base-burner anthracite-coal stove. To make it healthful we would not live in one room, but in two or three large ones, thus having lots of air-space, and then we would arrange for plenty of ventilation. We looked for a stove where we could see the fire burning all around, so that it would be just as cheerful as a grate. As for comfort, after quite a trial (this is the fourth winter) we think we have found a pretty good supply of it.

Before going further, please notice the arrangement of the main rooms below, as shown in the accompanying plan. This plan merely gives the outlines of the body of the house, without showing porches, bay window, pantry, kitchen, etc. This is sufficient for the point I am trying to bring out in this letter. You will notice, that from the dining-room into the bedroom, and also into the parlor, or living-room, there is a wide double door. These doors are eight feet high, so that, when open, the three rooms are practically one. The stove shown is in a position so central that it radiates heat readily into all the rooms. The doors may be closed so as to warm the dining-room, and either of the other rooms, or the dining-room alone. Ten or fifteen minutes' work will take care of the fire for 24 hours. Directly over the stove is a register opening

into the hall above. From this hall are doors into five bedrooms. The chill can be taken off in these bedrooms, if desired, although a stove upstairs in the writer's office generally answers this purpose. The double doors opening into the bedroom open back into that room, one on each side. Of those opening into the parlor, one is hung on the other, and they fold around in front of the chimney.

As I have written before, our kitchen was built for work. It is just the same size as Prof Cook's. We eat and live in the *best of the house*—perhaps I should say in the *body* of the house, as the kitchen is just as nice and pleasant as any other room. I pity those poor people who live almost exclusively in the kitchen, or a rear dining-room, perhaps, and open up the main body of their house (not home) only when they have company. I am happy to say, that my wife thinks her husband and children are just as good as any other company. How I dislike to visit where they have to go and build a fire in the best part of the house, and be thrown all out of the regular order of things by my arrival!

As we use it, our stove burns about 4½ to 5 tons of coal between, say, Sept. 15 and May 15. I paid last summer \$25.00 for 5 tons—not a very large sum for the comfort. The fire, of course, never goes out. To keep the entire house warm, upstairs and down, would probably take 8 tons. As to healthfulness, as we use it we consider it all right; but a base-burner in a single room, poorly ventilated, would be another matter. When the children have company in the evening we give them the house below, and wife and I go to our large room (my office, 16x18) upstairs. The floor of this room is deadened, so we hardly notice any racket that may be going on below. The bedroom below is used for company.

I have written to you in favor of sunshine in our homes. There are 9 large windows and 2 glass doors in the three rooms. Our room (wife and I) upstairs has 4 large windows, and in a bright day in winter the sun will almost warm it.

I should, perhaps, call attention to the fact, that, with a large (a little too large rather than too small) base-burner, properly managed, a gentle, uniform heat can be kept. The stove never becomes redhot, thus burning up the air. One can avoid being too hot one hour and too cold the next, as is often the case with wood-stoves or cheap soft-coal stoves. It is partly on this account, I think, that we have not had more than one-fourth as many colds in our family for the last three winters as we used to have; in fact, they are almost unknown.

Hudson, O.

T. B. TERRY.

I believe, friend T., that I agree with you in the main. I suppose you are aware, that your base-burner could be arranged so as to take pure air directly from outdoors, without very much more expense. With the large number of rooms you have communicating with each other, however, I do not believe I would advise this. It takes very much more fuel, especially during zero weather, where all the air we require is brought by a cold-air pipe from outdoors. We have tested, at different times, almost all arrangements and appliances for heating. I do not like a furnace in the cellar, because there is always more or less liability of leakage that will permit coal gas to come into the rooms. New furnaces often work without this trouble for two or three years; but when

they get old there is great liability of trouble of this kind. Where circumstances are favorable, steam does the business nicely, and the heat may be distributed and made to come exactly where you want it, and no heat where you prefer none. By the way, I presume you meant you would like to keep your potatoes at a temperature of about 34°; and that whenever the weather is cold enough you keep it pretty nearly there. To keep it at all times at or about 34° would require the very best modern appliances for cold storage.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

FOUNDATION OR NO FOUNDATION.

MR. BASS objects to empty brood-nests, when hiving swarms, on the ground that, in his locality, the yield is slow. At the Indianapolis Convention, Mr. Poppleton suggested that my *success* might be attributable to the same reason; viz., a long, slow flow. I do not think the success of my plan would be materially affected by either. If the flow is abundant, the bees are furnished all the *fdn.* they can draw out in the supers; while if it is slow the bees certainly have abundant time in which to draw out *fdn.* in the supers. If they can only be started, at the outset, to working with a "boom" in the sections, there will be no crowding of the queen, nor building of drone comb, unless the queen is about to be superseded. Mr. Bass made the mistake of using too large a brood-apartment.

I guess you are right, friend Root; the matter is more complex than it appears upon the surface, and the publication of a few short articles scattered through the various journals does not present the subject in the best possible manner; and I am going to thankfully accept your suggestion and "roll up my sleeves," *mentally*, clear up to my shoulders, and write a little book covering the whole subject of comb-honey production, as I practice it, and have it published in time for use next spring.

W. Z. HUTCHINSON.

Rogersville, Mich., Jan. 7, 1887.

CAN BEES FROM TWO DIFFERENT QUEENS WORK HARMONIOUSLY IN THE SURPLUS-BOXES?

I have received the first three numbers of *GLEANINGS*, and must say that I am well pleased with it, as an exponent of advanced apiculture. I wish to ask two questions. First, if I make my hive long enough to hold 16 frames (Gallup), and put a solid division-board in the center, with perforated zinc honey-board over all, and two entrances, one on the south and one on the east, the queens being thus confined to their respective chambers, would the bees work agreeably in the upper story of the hive? If so, would there be any advantage in such procedure? Second, are bees more liable to store pollen in sections 1½ inches thick than they are in thicker ones?

J. M. CRUICKSHANK.

Lyons, Ontario, Canada.

The plan you give will not work with any certainty for any length of time, friend C. During the rush of the honey-season, bees from different hives *may* mix up indiscriminately; but as soon as the honey-flow is

over, one of the queens will be balled, and you will eventually have but one swarm of bees. The matter has been thoroughly gone over by having division-boards that shrink, and letting the bees pass through or over them. I think likely the queen would be more apt to go into the sections where the latter were so much nearer the thickness of an ordinary brood-comb, although I have not tested the matter from experience. Can any of the friends inform us?

ALSIKE CLOVER FOR THE SOUTH.

I see in *GLEANINGS* that you advise Southern bee-keepers to plant alsike clover to better the quality of Southern honey. Will the clover do well here? Will the Chapman honey-plant do? My place is on the Brazos River, subject to overflow occasionally. Will the clover stand it? I saw Dr. O. M. Blanton's report (*GLEANINGS* for Nov. 1), and he says cypress barrels are the best that he has ever used. Won't the honey taste of the cypress, and ruin the sale of it—if there is any? Dr. B. is an old bee-keeper, and should know. Won't iron hoops do on the cypress barrels, as well as wood? C. F. Muth's price for oak barrels is \$2.00, without any inside coating or paint. They cost here about \$3.00—too much. I find that people don't want to pay for barrels or any other vessel. I receive letters wanting me to ship honey to them on commission, one from Chicago; at the present prices the freight would cost more than the honey would sell for. Some of the parties writing don't give references.

J. W. PARK.

Columbia, Brazos Co., Tex., Dec. 24, 1886.

Friend P., I can not tell you whether alsike clover will do well with you or not. It can be settled only by experiment. But I think you can be sure of this, any way: It can be raised in any locality where red or white clover will grow.—The supposition is, that the Chapman honey-plant will grow anywhere—or, at least, I should feel safe in saying in any place where thistles will grow.—I am not acquainted with cypress for barrels. Will Dr. Blanton tell us about it?—Be very careful about shipping honey—not only to *whom* you ship, but ascertain beforehand, as near as possible, whether the transaction promises to be a paying one. I understand it is not very unusual for commission-men to sell goods for only enough to pay freight, cartage, and commission; and I have known of some commission-men who were very cool about such transactions. It seems to me a fearful way to do business; and if any commission-man has any regard for his patrons, it seems to me he should manage in some way to avoid having goods shipped him, to meet such a fate as this.

HOW TO EMPTY THE HONEY-SACK, WITHOUT INJURY TO THE BEE.

I have often noticed, by writers in bee-journals, and some, again, quite lately, in *OCT. GLEANINGS*, as well as one number of the *A. B. J.*, where bees are dissected for the simple purpose of getting their honey. As this is not only a tedious and unnecessary operation, and, for that purpose, imperfect, I beg leave to inform the readers of *GLEANINGS* of a better and more simple way, and one, also, which will spare the bee from any harm. Take the bee the usual way, with both wings be-

tween the thumb and first finger of the right hand. The bee will then put out its sting. Now press the sting gently against something hard—wood or glass: keep on pressing, and keep her as straight as possible. Her extremity is thus made to press against the honey-sack, which compels her to force up to her mouth whatever she has, honey or water, and show you the drop, large or small, between her mandibles. This can then be taken from her with the head of a pin or a pen-knife point, in the left hand, for examination, and the bee left to go for more. If I want to only see the honey or water, I press her against my left thumb-nail, let her swallow it back, and let her go. Several bees can be examined in a minute, as they come dropping on the alighting-board, if desired. C. H. LUTTGENS.

Hammonton, N. J., Dec. 21, 1886.

If we understand you, friend L., your plan is something like the closing-up of a telescope. The abdomen of the bee is contracted lengthwise, producing a pressure upon the honey-sack, causing its contents to be forced out. The idea is certainly an ingenious one, and the bee-keepers owe you a vote of thanks, especially since it helps us to preserve the lives of our little pets. I have seen men take up their beautifully marked Italians as they came in laden from the fields, and coolly disembowel them; but I confess, my opinion of a man who does this falls a notch or two, in spite of myself. I have many times been very anxious to know what the bees were gathering, but I did not like to kill a bee to find out. Once, after I had watched nearly half an hour to satisfy myself, I saw a bee alight with muddy feet, and then I guessed they were carrying water, and I traced them directly to the brook. By means of your invention I could have satisfied myself in an instant.

A PLEA FOR THE SABBATH: HOW TO MAKE SUNDAY SWARMS COME OUT ON SATURDAY.

Several years ago, when I first began keeping bees, I was too ignorant of their habits to make artificial swarming a success, and knew no other way to care for natural swarming than to watch them "through thick and thin," Sundays and all days. Later on, I began to watch only at such times as colonies were about sealing their queen cells. After two or three years my stupid brain took in the situation, and since then I have not stayed at home on Sunday to watch bees. Bees swarm with the sealing of the cells or first cell. Knowing this I keep cells built, during swarming time, from my best queen in a manner costing no extra time or queenlessness of stocks—always, however, being careful to keep the dates, so as to know when a cell will hatch. In order to prevent swarming on Sunday, I look the bees over on Friday about noon. The experienced eye will detect at once such colonies as will be ready to cast swarms in 2 to 4 days. To such give a sealed queen-cell, slipping it between the frames, and on Saturday you may expect, almost with certainty, a swarm from that hive. I give this for those who, like myself, are obliged or prefer to have a day to themselves occasionally, and leave the apiary alone. This method is quick and effectual, Italianizing from your best queen at the same time; and last, but not least, having the Sabbath to yourself. This plan is original with me,

yet I doubt not others have thought it out as well; yet I have never seen it in print. I usually clip my queens' wings. C. M. GOODSPEED.

Thorn Hill, N. Y., Jan., 1887.

Your idea of obliging swarms to come out when you wish to have them do so is not entirely new, friend G. I know it will sometimes work as you say; but it is my impression, that a good many times it will not. We shall be glad to hear from others who have tested it.

QUEENS BY SPECIAL DELIVERY.

As the delivery system has been extended to all mail matter as well as to all postoffices, it occurs to me that it will be a good thing for queen-rearers as well as for the purchasers. When any one orders a queen, he, of course, wants her as soon as possible. Now, by sending ten cents in addition to the price of the queen he would get her just as soon as she can possibly come through the mails; and if he lives within the delivery of any free-delivery postoffice, or within one mile of any post-office, it will be delivered to him at once by a special messenger (see "Notice to Public," from P. M. General, posted in all postoffices). There are some whom this would not benefit very much; viz., those that receive only weekly or semi-weekly mail; but I think the majority of the purchasers would be benefited by it. Ordinary fourth-class matter is not attended to in the mails until the first-class has been disposed of, therefore it is more liable to mis-carry; but fourth-class matter bearing a special-delivery stamp will be disposed of before ordinary first-class matter, thereby going through with the greatest possible dispatch.

What do you think of it, Mr. Root? Why not say, in your catalogue, that, if ten cents in addition to the price of the queen is sent, you will send her by special delivery? As the queen-trade is over for this year it may come good next year, provided you approve of the suggestion.

S. E. MILLER, P. M.

Bluffton, Mo., Dec. 4, 1886.

Friend M., this matter has been suggested before; but before putting it in the price list, let us have some experiments to see just how it works. No doubt it will many times prove quite a convenience.

DOES THE BUSINESS OF HONEY-PRODUCING PAY?

I wish to ask a question or two concerning bee culture.

1. Is it your candid opinion that the bee-business, when strictly confined to the production of honey at present prices, can be made a success financially?

2. How many colonies of bees will the flora of any one locality support profitably, where there is considerable woodland, and where the white clover abounds in its season? I see there is considerable controversy on this subject, some maintaining that less than 100 will sufficiently stock a district bounded by the distance of flight of the bees from any given place in the working season, while others claim that many more may be profitably kept. I think that, with your experience, you will be able to answer the questions satisfactorily. RICHARD L. CLEGG.

Peoria, Union Co., O., Dec. 20, 1886.

Friend C., I do not know how it is possible to answer such questions as yours. It is just like asking if the strawberry business pays. The answer would be, with some

people, that it pays splendidly; but with a great many, perhaps it does not pay expenses. Again, no one can tell what a locality will do until it has been tested, and this applies both to soil and climate. By reading the reports given in every number, you will see that the bee-business pays *some* people. We also try to have reports in every number, from those who do not make it pay. In regard to the number of stocks in any one locality, it is rarely profitable to keep more than 100 in a place; yet very good results have been made from 150 and sometimes 200 on one spot. I am of the opinion, however, that 50 colonies will gather more honey *per colony* than will a larger number.

AN APPEAL TO THE HONEY-BEE.

Pretty little busy bee,
Don't you make yourselves so free,
Raising cane among your neighbors
With your tiny pumps and sabers;
Going into people's houses,
Crawling up the legs of trousers,
Getting your protectors blamed—
I should think you'd be ashamed,
Stealing sweets from choicest fruits—
Better stop, you little brutes.
Better spend your leisure hours
Pumping nectar from the flowers—
See what a rumpus you are raising
By your everlasting hazing.
Now can't you look this matter over
And get your nectar from the clover?
There's lots of room in fields and glen—
Go there and get your honey, then,
And don't be putting on such style—
Quit buzzing people all the while.
I'll try you just another season,
And see if you have any reason;
But if you've not, I'll not abhor you,
But have a little reason for you.

J. K. SWIPES.

PHENOL AN EFFECTIVE CURE FOR FOUL BROOD.

If you feed your bees in the early spring, to promote breeding, or even if you do not, make candy as per the A B C book; and when making it, add to it the proper proportion (I use 1 in 700) of phenol, as given by Frank Cheshire. Place the same on top of frames at the proper time, and note the results. In my experience every vestige of the disease will have disappeared unless the colony was too far gone. Please try it, and report for the benefit of others. When I first took up bee-keeping I was very enthusiastic, and wrote considerably for the bee-papers. Well, my friend, let me tell you that, though I have had considerable experience since then, I don't know as much now as I thought I did then; and, though I am learning every day, yet I don't feel so much like rushing off to print it as I did. A BEE-KEEPER.

A PUMPKIN BEE-HIVE.

We take the following from the Santa Maria (Cal.) *Times*:

One day this week Mr. Shuman, who resides a few miles west of town on the Guadalupe road, was gathering his pumpkins. He placed one on the wagon, from which he noticed bees issuing. Examination revealed the fact that the interior of the pumpkin was full of honey; in fact, it was a veritable bee-hive. The bees had gained access through a crack in one side of the vegetable, and had taken up permanent quarters. Mr. Shuman took out eight pounds of fine honey. Is there any other land under the sun where the farmer can raise his own pumpkins and honey on the same vine?

Perhaps some of our older readers remember this matter is not new, after all. Some years ago the matter of having bee-hives made from the sugar-trough gourd was discussed. Surplus-honey receptacles were to be made of small gourds stuck to the side of the larger one, at the proper point. We should then have not "sugar in a gourd,"

but honey in a gourd. Probably gourd bee-hives can be produced cheaper than any thing else—that is, if we were going to discard movable frames.

A COLONY OF BEES IN THE OPEN AIR, WITH THEIR COMBS FASTENED TO GRASS AND WEEDS.

Inclosed, a dollar you will see.
For which send GLEANINGS here to me.
By experience, I have found
It is useful, the year around.
In winter, spring, and summer too,
It will tell us what to do.
It also tells us where to find
Queens and supplies of every kind.

In the August No. we read a short but interesting account of "How Bees Work in the Open Air in California." It reminds me of the work of a colony in Northern Indiana during the past season. Instead of building their combs to the limb of a tree, they made their house in the tall grass and weeds. The combs were attached to and suspended by only grass and weeds, and the outer ones were built so as to partially protect the inner ones from rain, etc. Of course, this answered very well for summer, but I am afraid they are not provided with very good winter quarters.

DOES COLOR IN CLOTHING ANGER BEES?

A few years ago, when I first caught the bee-fever I visited the apiary of a German bee-keeper at Valparaiso, Ind. He had in the yard at the time, 90 strong colonies, mostly hybrids, and I thought them about the crossbred bees I had ever met. I had hardly stepped out among them before they commenced operations on me; and as they went at me in force it is hardly necessary to say I retreated. My friend dropped a hint then which I have never seen expressed in a bee-journal; but from experience since, I believe it to be true. He said, "Didn't you know dat bees shust hate black clothes?" He always wears a light-colored suit while working in the apiary, and gets fewer stings in consequence.

Westville, Ind. E. L. REYNOLDS.

G. M. DOOLITTLE, AND HOW DOES HE WORK OVER THE HIVES?

Inclosed find \$1.00, for which please send GLEANINGS for 1887, as I can not get along without it. I like the picture so well in GLEANINGS, "The Apiarist at Work," that I can not help asking Mr. Doolittle to send his picture and a cut of his apiary, with him sitting on his work-bench. Any way, I should like to see 280 lbs. at work.

Bees have, so far, done well on their summer stands. They are snowed under at present, but I hope they will come out all right. J. C. MISHLER.

Ligonier, Noble Co., Ind., Jan. 6, 1887.

If friend Doolittle will comply, we will have an engraving made to satisfy friend M. and others of our readers.

FROM NORTHWEST MISSOURI.

I commenced the season with 48 colonies, two of them queenless, 5 or 6 weak, the rest from medium to good. I increased to 75, and obtained 5600 lbs. of honey—150 lbs. of which was in sections. I have about 350 lbs. on hand yet. The rest is sold at an average of 10 cents a pound. My bees are well supplied with natural stores. I never feed sugar unless my bees are short of natural stores. We have a very good country here for bees, and bee-men are scarce. I know of some very good locations in this part, and cheap, compared with most places in the North.

L. G. PURVIS.

Forest City, Mo.

SWEET CLOVER AS A TREE IN TEXAS.

Editor Gleanings:—You doubtless remember a note I sent you in October, about a plant which grows along the cliffs and rocky lands of our country. I also sent with the note a branch and blossom of the plant, or tree, you might call it, and asked you to name it, but you seemed to be surprised that I didn't know it was nothing but common sweet clover. Well, it's true that I never saw any sweet clover to know it, but supposed it was a weed or grain. For fear you might have made a mistake, or that you did not take much time to examine the branch sent you before, I send you a block of wood sawed from one of the branches, and I ask you to reconsider the matter, and see if you can find a name for it. It grows from six to ten feet high, and is sometimes large enough to make fence-rails out of. The timber is very hard and durable. The shoots are very straight, and often, while out hunting, I have used them for ramrods for my rifle.

J. P. CALDWELL.

San Marcos, Tex., Dec. 6, 1886.

In reply, I wrote friend C. as follows:

I never saw any sweet clover with a stalk as hard as the sample you send; but as it has the very familiar taste of the plant, I think there is no question but that it is the same thing we have here. With us, however, it always dies down in the winter. Do you mean to say that with you the same stalk grows year after year like trees?

Certainly, the plant grows year after year, like any other tree or bush. The blossom is very fragrant, and the mountains are strewn with its delicious flavor twice a year.

J. P. CALDWELL.

San Marcos, Tex.

From the above it seems there is no question but that sweet clover, in climates sufficiently mild, changes its habit to that of a hard woody tree. I presume the leaves, of course, drop in the winter time. The next question will be, Is it still a good honey-plant? If I am correct, with us it frequently produces two sets of blossoms in a season, especially where a severe drought causes it to drop its leaves and dry up.

HONEY FROM HARD MAPLE.

The honey I sent, I think no doubt was obtained from hard maple, a part of it. I had no honey-dew honey—never have had in this State. I get some of the same kind every warm May. The largest colonies get it—the small ones, never. This year I extracted the first of it the fore part of June. Next year I will watch and make assurance doubly sure.

We have much maple timber near us, and we have large colonies early enough to gather it, and I think we fail only when the weather is too cool for bees to work, or the colonies are too small to get it. All my bees wintered in the cellar, and were not brought out till April 15. I failed to get any to show. Their brood probably used up all they obtained.

We regard our last season's experience as 10 lbs. per colony in favor of outdoor wintering, on account of this early gathering. Another spring may not so prove, but we shall see; 80 colonies are now in the cellar, as nice as can be—have been in just a month; 115 are outdoors, which had a nice fly Dec. 11. I have no doubt my outdoor bees will

surpass my cellar bees in early honey by more than 10 lbs. next year.

T. F. BINGHAM.

Abronja, Mich., Dec. 20, 1886.

The subject of hard maple came up at the Michigan Convention, and I asked friend B. to send me a sample of the hard-maple honey. I thought perhaps it might be something like maple molasses; however, it tasted to me more like honey-dew; hence my suggestion, and the above is friend B.'s reply.

HOW TO MAKE MILK PAINT FOR COVERING HIVES, ETC.

I have been reading part first of *Our Homes*, and have commenced making drains, foot-paths, and cisterns, as per your directions. I should like to know just how you make the milk paint that stands so well; also directions how to make the very best kind of cistern for greenhouses. I have only one colony of bees left. I lost all the others by foul brood. I am very busy now with the greenhouses—no time for bees, but expect to try them in a cucumber-house before long.

E. GRAINGER.

Toronto, Ont., Nov. 23, 1886.

Friend G., milk paint is made by stirring water lime, such as is used for cisterns, in skimmed milk. If you can not get skimmed milk, use sweet milk. It will be much cheaper than paint; and if put on new rough boards it will stand for years. If the boards are old, and have commenced to decay on the surface, it will peel off, taking the old surface with it.—I should enjoy hugely taking a peep at your cucumber greenhouses.

THE LOW PRICE OF HONEY, AND ITS COST OF PRODUCTION.

I can not forbear letting you know how well I like GLEANINGS. I take several very interesting papers; but when I get GLEANINGS they all have to wait until that is read, even to the advertisements, for I am always anxious to know all that is going on in the bee-world, even to who has got something to sell, and what it is.

I should like to say a few words on a subject that is being ably discussed by several of our leading bee-masters; namely, the low price of honey. In the years gone by, bee-keeping has been highly profitable where any effort was made to make it so, and why? Simply because it was not very much of a business in those days. There were but few specialists then in the business; the farmers produced the most of the honey-crop, and but a comparatively small amount was then placed on the market, and it brought fancy prices. Now the large numbers of specialists engaged in the business are placing so many thousand tons of honey on the market that bee-keeping is being forced down to a business basis, and I do not think it is quite down yet. In the near future I expect to sell a nice article of comb honey for 10 cents per lb., perhaps for eight; but if I can get to winter my bees successfully, I am satisfied that I can raise it for that at a profit.

G. E. HUTCHINSON.

Rogersville, Genesee Co., Mich.

May I caution you a little in regard to being in too great hurry to get the price of honey down? It will get down fast enough without any such suggestions as you make. I think you will find it close enough work to produce comb honey at 12½ cts. wholesale, to

say nothing of 8 and 10 cts. Enthusiasm is a good thing, but it does not always pay debts and get us out of cramped places.

GETTING THE MOTH OUT OF COMBS BY MEANS OF SUN HEAT.

Moth worms may not trouble you any, but here they are very troublesome as soon as the combs are away from the bees. Picking them up with a pin is a long job, and sulphur fumes are not always handy. As there may be some who, once in a while, will have combs with worms in, I will give you my way of killing them.

When the sun shines bright and warm I take my combs, two or more at a time—this depends on how warm the sun is, and set them where it will shine directly in the cells. In a short time the worms will begin to hunt the shady side, when I turn the combs over and repeat the operation till the worms have all left, or are dead. By being careful, not a cell will be injured, even if the sun is warm enough to melt the comb entirely, if left a few minutes too long.

AUG. LEYVRAZ.

Francis, Fla., Dec. 24, 1886.

I have noticed, that when combs were set out in the sun, the worms crawled out of the cells, but it never occurred to me before that it was the heat of the sun that made them vacate. If your plan will scare them all out, it is certainly quite an item, especially where black bees are kept.

TENEMENT PLAN OF WINTERING.

When spring opened last season, we had 58 colonies with which to begin the season. Fifty of the number were in good condition to gather honey. Our crop, 3000 lbs. of comb honey in one-pound sections, and 1500 lbs. of extracted, was of extra quality.

Twenty-three colonies were wintered in chaff bee-houses, made to winter four and eight. They came out in fine condition. I think this plan of outdoor wintering is one of the cheapest and safest plans known, and one of the most convenient. As they are made adjustable, all bulkiness of hives in the summer time is avoided, and they are also a great protection in spring, against the cold wind. My apiary of 123 stands will be arranged on this plan in fours, two facing the east and two facing the west.

We have tried to see how much honey we could sell here at home, and I think we did well, considering that the number of inhabitants is less than one thousand. When we began to sell honey we held ours at 15 cents. In a short time the farmers began to bring in honey, selling it at 10 cents in the comb, but we have managed to get 10 cents on an average for it, and have sold 1500 lbs. at home, and expect to sell more. W. S. DORMAN, 58—123.

Mechanicsville, Ia., Jan. 12, 1887.

LICKING STAMPS.

See here, friend Root; don't object to people rubbing postage-stamps on their hair, as Mr. Waller suggests at the bottom of page 27 of GLEANINGS for Jan. 1, to prevent their sticking together. Your objection is, that if hair-oil is used the stamps will be greasy, and won't stick, and that "t'other fellow" might "lick his tongue on the stamp after it had been rubbed on greasy hair." Now, a better way is to not have that "t'other fellow" nor any one else "lick" postage-stamps at all. Sometimes

they get licked too much and don't stick well, and get lost from the letter or package. Just let them, that is, that "t'other fellow," and everybody else, lick, or wet the corner of the envelope, and then place on the stamp without "licking" it. If one has lots of letters or circulars to stamp, just lap a lot of them, leaving room for stamps uncovered, and, with a small wet sponge or cloth, wet all at once, and then put on a large number of stamps in a twinkling.

A. B. MASON.

Auburndale, O., Jan. 3, 1887.

NOTES AND QUERIES.

WILL BASSWOOD GROW FROM CUTTINGS?

WILL linden (basswood) grow from cuttings? If so, when should they be cut, when planted, and how should they be treated, from beginning to end? Will they grow as fast as cottonwood?

U. H. WALKER.

Sabetha, Kan., Jan. 10, 1887.

[They will grow from cuttings, but it requires an experienced hand to do it. The subject is fully treated in our back numbers. I think they will grow fully as fast as cottonwood. The cuttings require a special treatment that makes it somewhat expensive; and as seedlings are offered for \$10.00 per 1000 or less, the decision was that it would not pay to grow cuttings.]

ALSIKE FOR PASTURAGE.

Alsike makes splendid bee-pasture. It is hard to beat for hay for horses or cattle. They prefer it to any other hay.

S. H. F. SCHOUTE.

National, Iowa, Dec. 29, 1886.

AN APIARY NEAR WATER.

If an apiary is located near a river or lake, or on an island of 10 acres, would many of the bees be drowned?

CHAS. F. CLARK.

Cokeville, Wyo.

[Unless there are high winds or stormy weather, we think there will be very few bees lost, under the circumstances you mention; in fact, a few colonies have been kept under similar circumstances, with very good results.]

OMITTING SEPARATORS, ETC.

Please let me know if the criticisms of some friends against the practice of omitting separators between section boxes are well founded when the boxes are notched all around, as lately suggested, and I believe practiced, by friend Foster.

Knoxville, Tenn., Dec. 7, 1886. ADRIAN GETAZ.

[My impression is, friend G., that even with friend Foster's plan of working, we can not afford to omit the separators, if we want to have real nice straight honey.]

A REPORT IN REGARD TO BARNES BROTHERS' FOOT-POWER BUZZ-SAW.

I bought a new combined Barnes machine, with treadle, and a crank attachment. It was the fourth machine I have bought of their make. It is very much better than the old combined. I have used both.

G. M. MORTON.

Smithboro, N. Y., Nov. 27, 1886.

I should like to ask Ernest if he introduces virgin queens to nuclei in the same way as described on page 1000, Dec. 15.

GEO. W. COOK.

Spring Hill, Johnson Co., Kan., Dec. 22, 1886.

[I have never tried introducing virgin queens by the Peet process, as described in Dec. 15th issue, but I presume that it could be done. D. A. Jones claims to do it successfully; and if it can be done at all, I believe that the Peet cage will do it successfully.]

THE CHAPMAN HONEY-PLANT.

We find the following paragraph in the *British Bee Journal* for Jan. 6:

We may here mention, that Mr. Cowan informs us that he has grown *Echinops Spherocephalus* for eight or nine years, and classes it high as a bee-plant.

CAN FOUNDATION GIVE FOUL BROOD?

Don't you think foul brood can be spread from foundation made from diseased comb?

CHAS. H. VAN VECHTIN.

Victor, N. Y., Nov. 22, 1886.

[I do not believe it possible, friend V., for foul brood to be communicated in the way you mention. In making foundation we always melt the wax, and the temperature of melted wax is death to any fungoid or animal life.]

HOW \$3.75 INCREASED TO \$15.00.

I want to tell you about my bees. This summer, the last of June, I bought 1 lb. of bees and a queen, and put them on 10 frames of old comb, and they are a nice large swarm, now worth \$15.00, and they cost me only \$3.75 for bees, queen, expressage, \$1.00 worth of sugar, and my time. Pretty good, isn't it? Jackson, Mich.

CLARENCE W. BOND.

THE BARNES SAWS.

I write you in regard to the Barnes foot-power saws. Do you think I could saw four-piece sections with it? White poplar is what I intend to use. I am a rather stout man.

W. D. SOPER.

Jackson, Mich., Dec. 8, 1886.

[Yes, friend S., you can saw four-piece sections with the Barnes foot-power saw; but I think that, even if you are a stout man, you would begin to think of an engine before you had sawed many thousand, especially if you try to produce them at the figure they are now advertised. If you think best to try it, we should like to have a report from you in regard to the matter.]

FINE WIRE FOR SEPARATORS.

Have you ever tried fine wire stretched on your broad frames, about $\frac{1}{4}$ of an inch apart, for separators? I can't see why it would not answer, and be no hindrance whatever to bees passing in any direction through the openings in the sections.

D. S. BENEDICT.

Ludington, Mason Co., Mich., Dec. 20, 1886.

[We have never tried fine wire, friend B., although the matter has been suggested before in our back volumes. The difficulty of putting them on and keeping each one of them stretched tight is what deterred me from testing it. Besides, after we got them on, unless the wide frames were handled very carefully they would be very easily injured. If any of our readers have ever tried it, we should be glad of a report.]

A HONEY-CUPBOARD—HOW TO MAKE.

Will you please inform me how to inclose a honey-cupboard? I am making one to hold about 1000 lbs. of comb honey. A show-case will form the top to hold sections or prize boxes. Would you inclose the lower part with wire screen, to keep air to the honey, or with lumber?

F. S. THORINGTON.

Chillicothe, Mo., Dec. 2, 1886.

[Friend T., I believe it is not usual to keep such a quantity of honey in a cupboard; and before we can tell whether it had better be inclosed in a wire screen or lumber, we should like to know something about the room that contains it. If the room is one where it does not freeze, and the air is comparatively dry the year round, wire cloth would perhaps be best; but if there is danger of frost enough to make a precipitate of moisture on the surface of the honey, you had better shut it up as tight as you can, with boards.]

REPORTS DISCOURAGING.

THE HONEY SEASON OF 1886 ON THE LOWER MISSISSIPPI.

MR. EDITOR:—The honey season of 1886 is past, and for this locality I have to record an almost absolute failure. I began the season with 125 colonies, very strong.

A cold spell in April struck the apiary, and all of the strongest colonies were left with chilled brood. I lost over 20 colonies from this cause. Those hives had from nine to thirteen combs filled with brood, and did not have bees sufficient to cover the combs during the cold spell, and the brood died from cold; hence I had not one fair-sized swarm during the entire season. The cold, late, and wet spring hung on so late that I got only two barrels of white-clover honey, of a very dark color, with my 125 hives, compared with the $11\frac{1}{2}$ barrels of fine white-clover honey from my 67 hives the previous year. The bad weather hung on all season. The weather was so cool and damp that honey secretion was almost entirely suspended. My bees nearly starved during August, and only the strongest were enabled to raise brood enough to carry themselves over winter. Those deficient in brood late in the fall are dying off very fast, owing principally to the warm winter weather we have had so far. The bees will fly out and get chilled and are lost, thus depleting the hive of the bees so necessary in spring. Where this dwindling is going to stop, I can't say yet. I have carried in, so far, 15 empty hives. Almost all have plenty of honey, and none are in need, but the bees would be so few that they could not hold out, and died, in some hives, with honey all around them.

I put by, for winter, 85 colonies, left from the 125. I began the season with 70, and have that many now, some of which are very good, and many very weak. The warm winters are a great drawback to bee-keeping here. If it would get cold enough to compel the bees to stay in the hives till spring, one would have full hives of bees to begin business with; but the warm days allow the bees to fly out and get lost, and to wear themselves out with exercise in the hives; and, as a result, only the strongest hives, with an abundance of late-hatched bees, will be strong in the spring. How many more colonies will die out before March, is a question I can't answer. They don't want feeding, as they have plenty of honey, but many of them do want bees.

My yield last season was 35 lbs. of extracted honey per hive. This, with a loss of 55 colonies, and New York and Milwaukee for my markets, and a net price for my honey of a little over 4 cts. per pound, does not conduce to make me liable to lose my mind in my enthusiasm over bee-keeping in Louisiana—at present, at least. When I read of Dr. O. M. Blanton's little report of 70 lbs. per colony and 60 barrels, I felt he ought to be ashamed to complain. What would he do with only 35 lbs. per colony? I have tried to look somewhere for the traditional ever-present silver lining, but I haven't seen it yet. It may yet come from behind the plainly visible, lowering, dark-gray storm-cloud gathering in the west; and when that passes by I may look again upon pleasant sunny weather with my bees. In the meantime, I'll wait and see.

Hahnville, La.

3—C. M. HIGGINS, 125—70.

MYSELF AND MY NEIGHBORS.

And why beholdest thou the mote that is in thy brother's eye, but considerest not the beam that is in thine own eye?—MATT. 7:3.

IT was at the close of the Sunday evening prayer-meeting, and my sister was speaking about the revival held at one of the other churches in our town. She said the pastor of that church had wondered I had not been present, for he supposed, from what he knew of me, I could not stay away when a revival was going forward. As it was near church time I passed along with the crowd and was soon seated right in front of the pulpit, the usher probably thinking that there was where I ought to be. The revival work was conducted by a lady. I had heard her speak once before on temperance, and I was not very favorably impressed with her abilities. As an illustration, among other points she made she called attention to the fact that farmers have much more trouble in getting their corn to come up in the spring, of late years, than they used to have. I am well aware of this, and our agricultural papers have discussed it. But the speaker gave as a reason, that it was God's judgment on the farmers for selling their corn to the distillers. As she stood before me that evening my mind reverted to the incident above, and I could not or did not have very much faith in her ability to lead souls to the cross. As I looked about among the people that were gathered before me, without hardly knowing it I was encouraging a disposition to criticise the friends and neighbors around me in the same way. The large church soon became very much crowded, and seats were placed on the platform, close up to the pulpit, so that many faces were before me, and a grand opportunity was afforded for studying humanity. I profess to have much charity, and love for unity among the churches, and I have often exhorted toward this same charity and love for our neighbors among the various churches of our town. But this evening it was very natural to see faults, not only among those of my own sex who had gathered there in their Sunday best, but even among the young people of the opposite sex. I have before alluded to this temptation of mine; and as it comes up every now and then, I presume it must be one of Satan's strong points with my poor self.

During the first half of the sermon I found fault with most that was said. The text was "Eternity," and the speaker pictured hell in horrible colors. She said eternity is so great, that, if a bird could fly from the sun to the earth, and take a grain of soil in its bill and fly back again it would, in the process of time, carry this whole earth to the sun; but this great period of time would be as nothing compared with eternity. The thought was, that everlasting punishment would be ages and ages longer than the lapse of time illustrated by the above figure. I want to say here by way of parenthesis, that, to *my way of thinking*, such illustrations are not wise or in good taste. It seems to

me we are transgressing on the domain of the Almighty when we use figures of this kind; and very likely I shall always think so, even though it is a fact that ministers of various denominations are in the habit of using such figures quite often.

She changed her theme toward the close, and her talk fell in with my line of work. She spoke of visiting the jails and prisons, and finally I so heartily indorsed the grand points she made that I should have felt guilty had I kept silent. I added emphasis to one of her remarks by an earnest "Amen." Now, please have charity for me when I tell you that, heretofore during the sermon, I had, much of the time, turned my eyes away from the speaker. I disliked her, and her face was not pleasant to me. After that indorsement by the amen, I began to see something different in her expression—something that was pleasant and attractive. Christ's spirit seemed to shine forth from her countenance. Soon after I caught a glimpse of some of the faces near her. How strange! Christ's spirit seemed to shine forth *now*, from those faces also; and as I looked about me the whole audience had been transformed. Instead of narrow-minded people, and people whose faces showed a lack of intelligence, I beheld humanity in the likeness of God the creator. Had *they* changed under the influences of the earnest preaching? Why, bless you, no, dear reader; *my own heart* had changed, and the people and the speaker were exactly as they had been. Christ's spirit had *finally* found a lodging-place in my own heart; and is it at all wonderful that I loved everybody? Their faults and imperfections had faded away off in the distance, and the charity and love in my own heart enabled me to see their lovable traits, and the God-like part in them all.

The services lasted a good while, and it was late when I got home; but for all that, as I told my wife about the meeting, and knelt by our bedside, I prayed that this better spirit might go with me through the coming week. That prayer was answered. Are not *such* prayers *always* answered?

I want to stop a minute, however, before considering that coming week. Others may have felt like criticising our public speakers and evangelists in the same way I have mentioned. Well, suppose our sister *did* say that it was selling corn to the distillers that caused the trouble with the seed corn; and suppose, too, she *did* picture eternal punishment in such awful colors as to frighten the youngsters, who shall say her figure was overdrawn? Ask our best thinkers of the day how terrible are the consequences of choosing evil rather than good. I have seen men deliberately decide to follow Satan. I have seen them go down step by step. I do not know where the end will be, but I think it very likely that neither *human tongue* nor *human imagination* would be able to picture the terrible consequences of such a choice. Why, then, should I find fault with the speaker?

Among the thirty or forty that gathered to the anxious-seat at the close of the meeting, there were a good many children. There

was one boy who used to swear on the streets so fearfully that the neighbors all felt troubled about him. There he stood right before me with penitential tears in his eyes; and when the speaker, in motherly tones, gave him Christian counsel and encouragement, I inwardly prayed that God might spare and bless her even more abundantly. When I saw the teachers from our public schools join in the work, and come forward to the anxious-seat to exhort and encourage their pupils whom they found there, I said in my heart as did Jacob, "Surely the Lord is in this place."

I felt the influence of that meeting during the whole week. During the first day of the convention at Albany, the low price of honey was discussed, and several of the honey-producers felt as many of our farmers do now, a little sore about the price they were receiving for their products, and they very naturally felt like blaming somebody. One speaker made some remarks in regard to the middle-men and commission-men. Another suggested that the latter were a useless class, for they get all the profit while we do all the hard work. A third condemned them as a whole, and some of the terms he used were not very complimentary. I began to feel that they were getting into the same spirit I was when I first sat down in that revival meeting, and it seemed to me as if God called on me to enter a mild protest. They readily gave me the floor, and I asked if it were not probable that there are good men and bad men among honey-dealers as well as among honey-producers.

"Dear friends," said I, "let us be careful how we condemn indiscriminately any class of people; and, above all, let us not say unkind things of any brother *behind his back*. If a bee-keeper has plenty of time, and with it the ability to retail his honey, or to furnish it in any way directly to the consumer, *by all means* let him do so; but if he has other business that pays him fair wages, and if, like many of us, he has discovered that he has no talent for *peddling* and selling in little dribs, by all means let him employ somebody who *has* this talent, and then every thing will be pleasant and there will be harmony. If a middle-man pays him so little that he can not afford to employ him, it is his privilege to trade some other way. If the commission-man he selects fails in selling the honey at the price wanted, try some other *man* or some other *way*; but through it all, let us have charity."

There was another thought I did not give then, because I did not wish to take up so much time, but I will give it here. At the convention, middle-men were accused of *doubling* on the honey, when they buy, and sell at *wholesale*. This may be true in some instances, but I think not often. Middle-men often have many vexatious losses as well as ourselves. A. C. Kendel, of the Cleveland Seed Store, invested several thousand dollars in a cold-storage room of the most approved construction. The very first year he tried it he lost \$2000 clean cash; he lost it, too, I verily believe, in trying to help farmers and producers, by taking produce when the market was glutted, rather

than have it a total loss to the producer. During the present winter, however, with the benefit of the experience of the year before, he has succeeded so finely that he has already pretty nearly or quite made up for the losses of a year ago. At the Forest City House, where we took dinner, grapes and other fruit were on the table, from his cold-storage room. They were as fine in the middle of January as any fruit I ever ate at any season of the year. Now, friends, I have no doubt but that Mr. Kendel is getting twice as much for those grapes as he paid for them; and one who has no conception of the care and anxiety, as well as money it cost to enable him to do this might say, "Just look at it! he paid us only 4 cts. a pound for those very grapes that he is now selling for 10 and 12 cts." The above figures are given at random, only by way of illustration. One thing I do know, and that is, that middle-men are often obliged to sell honey as well as fruit at a great loss; they take risks where they buy things of this kind out of season, and they must have their profits. In my remarks I suggested, if I am not mistaken, that we should invite the honey-dealers to be present at our conventions, that we might hear both sides of the question. About this time our good friend L. C. Root suggested that one evening be devoted to the consideration of the honey-market, and that middle-men, commission-men, honey dealers and consumers, be invited to be present and give us their views. Accordingly an evening was appointed; and as the invitation was given through the press, a large number were present—perhaps 200 or more. During the midst of our talk a fine-looking young man came up hurriedly to the platform, and threw off his overcoat with an air that seemed to imply that he was squaring himself for a fight. His first words were something like this: "Ladies and gentlemen, I am a middle-man;" and then he gave us one of the finest talks in regard to the sale of honey I have ever heard in my life. Some one had doubtless repeated to him the unkind words that were uttered the day before, as seemed evident from some of his remarks. His name is Mr. Henry R. Wright, and his place of business is 328 Broadway, Albany, N. Y. I extract the following report from his talk as given in one of the Albany daily papers:

"I sell honey; I am not a producer. I consider honey a staple, not an article of luxury. I think the low prices due to over-production. I should like to see a uniform style of comb adopted, something like this. [The speaker exhibited an unglazed frame which would contain a comb and about 11 ounces of honey.] Two-thirds of the honey produced is buckwheat. I sell 100 cases of buckwheat to 10 of the others. I sell from \$10,000 to \$20,000 worth of honey a year, and I don't make a specialty of it either. [Applause.] My experience shows that an unglazed package of about 10 or 11 ounces that will sell for 10 cents is the most popular, and if a uniform package of that size could be adopted it would increase the sales of honey, and be of benefit to the producers."

The speaker had a number of the frames of the size shown by him disjointed, and he said any one who wanted one could have it. There was a scramble among the members, and the frames soon disappeared.

The little frames he exhibited were about the width of our one-pound section—perhaps a little narrower. They were oblong, something the shape of a testament, perhaps. He prefers them oblong, because, as he expressed it, it made more of a show of surface of comb honey. The reason he preferred buckwheat to basswood or clover was because it enables us to give consumers a bigger chunk for a dime. His whole enterprise is based on the idea of selling the honey at 10 cts. a cake. I replied to him, and suggested that we use the ordinary Simplicity section, $4\frac{1}{2} \times 4\frac{1}{2}$ in., making it thinner instead of smaller or different in size. But his experience had been entirely with the oblong section. As buckwheat is so rarely in sections in the West, we should probably need to make ours so as to hold a little less than 10 ounces—say 8 or 9 ounces. Mr. Wright told us he had sold from \$15,000 to \$20,000 worth of honey in the city of Albany during the last year, all put up in the kind of sections recommended. He said the supply had been out for some time, and he would be glad to contract for a large amount of this honey for another season. I do not know whether he is prepared to answer inquiries in regard to this matter or not; but I do believe the coming honey-package is something that can be retailed for an even dime. One of the strong points he made on it was, that any average family will eat it all up and "clean up the platter"; there will be none of it left to set away to daub the dishes and draw the flies. Besides, a great part of the laboring population are in the habit of buying their supplies for the table, 10 cents' worth at a time. If you will tell them the price is 12 cents or 15 cents, they won't buy it. If it is only a dime, off it goes. Mr. Wright does not retail at all. He furnishes grocers and retail dealers. I do not remember how many of these 10-cent sections were in a crate, but I suppose it does not matter materially—anywhere from 12 to 24, perhaps. He takes the honey all on commission. Two-thirds of the value is paid in cash to the producer when the honey is laid down, and the remainder when sold. He buys by *weight*, but the consumer purchases, as I have said, by the *piece*. In view of this it is desirable that the sections of honey should weigh as nearly alike as possible; and to do this we shall have to use separators. Now, then, friends, all these valuable points were brought out by a pleasant and friendly talk with one of our much-abused *neighbors*; and the moral to my little story to-day would be this: May be the neighbor whom you are abusing and calling names is this minute both able and willing to help you very materially if you will treat him as you should always treat *every neighbor*.

Since the above was written I have talked with our foreman about this dime section; and as it is very near the dimensions of the sections we make and keep in stock, known as six to the L. frame, perhaps this will be the most desirable size, as it will fit all of our hives and packages. If we are to sell clover and basswood honey for 10 cts. a section, we can not have it contain more

than 8 or 9 ounces; and to do this, the section mentioned above, six to the L. frame, will need to be about an inch in thickness; if separators are used, may be $\frac{1}{2}$ inch. Have any of our readers ever experimented on a section of this size? The comb, you will notice, will be about of the thickness of an ordinary brood-comb. It will be a little card of honey for 10 cts. Mr. A. A. Rice, of Seville, O., has sold sections quite similar to the above. He gets them filled by putting them in an ordinary brood-frame in the lower story or the brood-apartment.

OUR P. BENSON LETTER.

ROOLS FOR SWARMIN BEES.

BEES has to be swarmed evry summer.

Thay cum out to be swarmed of thair own ackord. Moastly on a hot day.

Hwen thay cum out, poot on a overcoat—fur is best. Thay like to feel the soft fur and will role over and over in it, forgittin to sting. Poot on thick woolen mittens and ty a string around the rists. Also ty up the ankels. Poot on a son bunnet and ty it tite around the neck. This will maik you middlin warm.

P. BENSON, A. B. S., REDDY FER STINGS.

Then go out and look if the swarm is still thair. Git three (3) vales and ty over yure son bunnet. If you hed only one (1) vale the bees mite chaw throo it. This will maik you a little warmer.

Tell yure wife to look you all over kind o careful like and see if thair izzent a hole ennywhair whair a bee mite break throo. Then go and git a hive. If you hevvent got enny, that will be better. You ken go over to the nabers to borough 1, & it will amoose the naber's childern to see you drest up so comfortable like. You woont ken git enny to the nabers so you ken cum home on a run and maik 1 out of a old box or nail keg. This will help to warm you. I forgott to say that hooverer 1st sees the swarm cum out must yell for the rest, & all hands must kommens to keep up a noise. The oald wooman ken pound on a tin pale with a pint dipper, another ken bło a horn, and 1 ken jinggel a cow bell, and 1 ken hammer on a tin pan, and 1 ken hammer on another tin pan, & all ken holler, exseptin the horn,

he kant holler. Keep the noise & racket agoins steady. If thay is enny nabers thay cood bring sum moar tin pales & things & maik sum moar racket.

After you git yure box or nale keg reddy, rub on sum tanzy tea. This will help to charm the bees, but I cood sell you a bottel of P. Benson's Bee Hive Elicker that is shure evry time. Another time I will tell you whot els to doo, but keupe up the racket till then.

P. BENSON, A. B. S.

P. S.—Printer poot in that A. B. S. stans for Apiculturalistical Beekeepin Sighentist.

THE CONVENTION AT ALBANY, N. Y.

CONTINUED FROM PAGE 46, LAST ISSUE.

THIS convention was one of the best and most profitable that it has ever been my good fortune to attend. To give in detail an account of all the valuable things that came up and were discussed, would make quite a book in itself, therefore I shall have to notice briefly the most important points.

The question as to what to do with our honey was the most absorbing topic, and there was some considerable complaint of overproduction, but not quite the customary amount of censure because somebody else had done or had not done so and so. Blaming editors of bee-journals for urging everybody to go into the business, occupied a portion of the time. Then came the question, are there too many already in the business? and is it best for some of us to give it up? Mr. L. C. Root, son-in-law of "Father Quinby," as he is called in York State, was one of the bright spirits of the occasion, and I understand he has been one of the old wheel-horses in the convention ever since its start. I learn, also, that Father Quinby was founder of this same convention; that he had met and taken part in its deliberations on the very floors of Agricultural Hall, which we were then occupying. I hope my two good friends, Prof. Cook and L. C. Root, will excuse me for saying that L. C. Root seems to be to the bee-keepers of York State just about what Prof. Cook is to the bee-keepers of Michigan; and I think the inhabitants of these two States may fervently thank God for two such men—men so devoted to the best interests of the youth of our nation; and men, too, who are laboring so earnestly to have godliness and righteousness prevail. Among other good things brought out by L. C. Root was a little talk which he prefaced with the following, in his own words, as nearly as I can recollect.

IS OUR PURSUIT A WORTHY ONE?

"Now, friends, before going very far in this matter of giving up the business because it does not pay, let us look at it a little. Is bee culture a worthy pursuit? Is the industry one we may be proud of? When a young man starts out in any sort of business, if he does not he certainly *should* inquire, 'Is this kind of work laudable, and will the world be benefited by it? Is it a respectable calling?' I am glad to be able to point to you the words of Holy Writ where it says:

Butter and honey shall he eat, that he may know to refuse the evil, and choose the good.

"Now, friends, there is more in this little verse, perhaps, than the world has ever brought out. The production of butter and honey was especially pointed out as worthy and laudable, in the Bible; and whatever is in the Bible will bear following. Many people find themselves greatly benefited by a diet of milk and honey; and in the text I have quoted, butter and milk amount to pretty much the same thing; that is, the industry that affords butter, of course affords milk. A great deal has been said here about the overproduction of honey. We are producing too much of it, hence the low prices. I want to say, there is no overproduction, if it were properly placed before the people, and they had an opportunity of using it. There are enough children in our land alone to take every pound of honey we can produce, and not have half enough to go around, even then. [Applause.] Instances have been mentioned during this convention, of cases where people had no sort of knowledge that good honey could be offered at retail for 8 or 10 cents per pound in its liquid state, and from 12 to 15 cents in comb. [Louder applause, etc.] We have produced immense quantities of honey. At one time the shipment of a ton of honey to New York created quite a sensation; but now, carload after carload may be unloaded at our commission-stores, and no note or comment is made of it. We are consuming immense quantities, but the world is by *no means* supplied yet. What is the trouble? One of the troubles, to my mind, lies right here, and it certainly is a very great trouble. The industries of our land are not all worthy and laudable. The Bible indorses and approves of the milk and honey industries; but does it anywhere say that beer and whisky shall ye drink, that ye may know to choose the evil from the good? [Loud applause.] Do you wish to know what the beer and whisky business has to do with the low price of honey? Just this, my friends: The money that should pay for milk and honey for the children, now pays for beer and whisky every Saturday night, and the children go without these things that would be so conducive to their health and well-being. [More applause.] You have all heard of the immense sums of money that go into the dram-shops. Now, a great part of these immense sums are made up of the money that is needed for the growing children; and I hardly need allude to the fact that a mere fraction of the money that goes for intoxicating liquors would take all the honey that we can produce, at good prices, and the honey would benefit, while strong drink is a curse."

I wish it were possible for me to give a good many more similar talks furnished us by friend Root; but I am afraid that a good deal that I have quoted above may be so far from his words that some of the friends may think I have not done him justice; but I have given the idea, and it is a grand one for the encouragement of the bee-keepers of the world.

Some very pleasant words were said in regard to reviews of the past. Friend Root

spoke of the progress we had been making in the matter of charity for each other. Said he, "Why, I remember the time when this convention spent nearly one whole day in censuring and finding fault with the editor of GLEANINGS and the editor of the *A. B. J.* The principal complaint made of our friend A. I. Root was his one-pound section. I am glad he is here to-day, however, and I am glad that the one-pound section is now the standard the world over. We complained then because of the smaller package he recommended. What shall we say now, when a dime package of comb honey seems to be the coming package?"

The subject of supply-dealers came in, of course, during the deliberations, and friend Root said he had urged the importance of bee-journals not connected with the supply-business, and he still felt that it would be very desirable, if it were possible, to have a bee-journal in no way connected or interested in the sale of supplies. He added, however, that, if experience seemed to indicate it best, all things considered, to have the editors deal in supplies, he was willing to give way and let the matter drop. He emphasized, however, a point which I wish to notice a little. It was this: That one who deals in supplies, and has no interest in any journal, does not stand a particle of chance of competing with the proprietor of said journal, on account of the editor's facilities for constant advertising. At that time I wanted to put in a word; but as so much was before the convention, and as it seemed a little like pleading for my side of the question, I let it drop. I will, however, give it here: Admitting that a bee-journal is a wonderful help to a dealer in bee-keepers' supplies, because of the reasons given, there is, notwithstanding, a far better way of advertising than through any bee-journal; and this better way is open to all and every one in any business of any kind. Shall I tell you the secret? It is, my friends, simply to surprise every customer you get, by giving him the goods he has paid for, before he expects them; and surprise every one who writes you a letter, by getting some sort of an answer to him before he supposes an answer could possibly have had time to reach him.

Had there been an opportunity for me to say this before the convention, I suppose it would have brought down the house with applause, for they applauded me for many things with far less truth in them than the above. Now, the above few words are of so very much importance to the thousands who are just embarking in business, that I want to digress right here in my report of the Albany Convention, long enough to explain a little how you may all avail yourselves of this wonderful means of advertising. If you are some distance from the postoffice, and go after the mail yourself, put some postal cards in your pocket. Open your mail at the office, and acknowledge the receipt of letters of importance right on the spot. It is a very great advantage to be located near a post-office and express office; and if you are going to build up much of a business of supplies, or sending goods by express or freight, you had better get a location that will admit

of promptness. When an order comes with money, start back a postal card, telling your patron what to expect; then bend your energies to the fulfillment of the order in such a way as to make friends with your customers. Now, then, get up early mornings, or be out a little after dark, if need be, to get the goods on an early train; and if you lose money by the time it takes to be prompt, on a single transaction, you are laying up money by building a reputation, and you are building on a solid rock.

After the convention was over, among the great numbers who wanted to shake hands with "Brother Root" was a young man of fine appearance and pleasing address. By the way, I have begun to think several times lately I was really falling in love with the boys of our land—with good boys—boys who do not swear nor drink, nor use tobacco—boys who love bees and outdoor pursuits—boys who love godliness and righteousness. Well, right before me was a model boy. He might have been 25 years old, but he was one of America's boys for all that. He was a schoolteacher; and it just now occurs to me that I love schoolteachers. May God help us in choosing teachers for our youth, who are upright in life and pure in heart. After talking with him a little I found out that his father was somewhat of a market-gardener, and that he himself was in love with intelligent agriculture. Need I tell you that we became fast friends very fast? When we got down to the Globe Hotel he applied for a room, and was told that the bee-men had filled the house completely—there was no room for another one. "Why, look here," said I to my friend, "if it meets your approval, room with me, and then we can talk bees and gardening."

He seemed to be very much pleased with the arrangement, and we had some big talks. I tell you. Next month I will give you the outcome of some of these talks; but I want to make only one point now. He, with many others, spoke of our wonderful promptness at the Home of the Honey-Bees, and, by way of contrast, he mentioned the following:

Early in the spring his father sent for section boxes, etc., for the coming harvest. He sent the exact amount of money, for he had previously received an estimate. The estimate came promptly; but after they had sent the money it was almost impossible to get a word from the supply-dealer. I do not know whether they even acknowledged the receipt of the money or not, but they did not send the goods, and did not tell when they would send them. The bees began gathering honey. As our friends could get no answer they asked to have the goods sent at once, or the money refunded; and in any case to let them know what to depend on, without a moment's delay. After nearly or quite two weeks had passed, our young friend, in desperation, went across the country with horse and wagon, and succeeded in getting some sections that were not at all what he wanted, although they cost much more than those that were ordered and paid for. After they got home with their odd-sized sections, and got part of them in the

hives, the goods that had been waiting for weeks and months put in appearance. But even then no word of apology, no letter of explanation, came. After the rush was over, came a very handsome letter of apology. I do not remember whether there was a proposal to pay the damages or not, but there ought to have been. My young friend stated, that a simple postal card, telling them just what they could depend upon, would have been worth more than ten dollars in cash. Now, then, do you see clearly the secret I have been telling you of—a secret that is worth for advertising purposes *more than all the bee-journals put together?*

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

HOW THE BEES HAVE WINTERED UP TO DATE.

IN my last, you remember I felt somewhat apprehensive as to whether the large number of nuclei with their valuable queens would survive the continued zero weather we were then having. Since this time we have had a day or two of beautiful spring weather, during which our bees all had a good fly. I am glad to inform our readers, that, at this writing, not one of our colonies, either large or small, has died. I opened, or peered into about 25 of the doubtful ones—the weakest and the strongest. The former I feared might perish from the cold, on account of the small cluster; the latter, because they might have consumed their stores. All were in excellent condition, and well supplied with stores. As the bees were flying from the entrances of all the rest of the hives (about 175), from which bees ought to be flying if alive, we decided not to open them up and disturb their winter nest. The colonies all had a great abundance of stores the previous fall, and we took it for granted they would hardly be needy by this time. In a month or so, when a warm day permits, we will examine all thoroughly, and all such as may be running short we will supply with combs of sealed stores. These latter we have stowed away for this purpose, in our honey-house.

While it is encouraging thus far, the bees have yet to encounter the changeable weather of spring, and I may yet realize what I at first feared.

VENTILATION.

For two seasons back, my attention has been attracted particularly to the fact that all colonies packed in chaff hives cluster close to the front side of the hive (providing they have stores in that quarter) just over the entrance. In pulling back the chaff, and lifting the burlap in the colonies that I examined recently, I found that the bees were invariably clustered over the entrance. Why do they do this? I believe it is wholly on account of better ventilation which they get in that quarter of the hive. Hence I think the wisdom of giving bees the full width of the entrance.

WHEAT OR OAT CHAFF.

One of our colonies was, by mistake, packed with oat chaff instead of wheat chaff, as the rest were packed. The chaff in this hive was wet and moldy, and even partly rotted. The wheat chaff, on the contrary, was nice and dry. I threw out the wet chaff and put some dry in its place.

CLEANING THE CLARK SMOKER FROM THE VALVE.

In order to obtain the best results, the Clark should be cleaned daily. Heretofore we have been obliged to clean from the nozzle, passing the wire cleaner through the blast-tube: but as the latter is not easily accessible through the nozzle of the smoker, C. C. Miller and others have suggested that the valve be made removable so as to permit the cleaning-wire to enter through the bellows into the blast-tube. Mr. J. T. Calvert, one of our co-workers, as you may know, and a brother-in-law of the writer, has struck upon the plan illustrated below.

THE CLARK SMOKER, WITH THE VALVE SO CONSTRUCTED AS TO FACILITATE CLEANING.

The engraving shows the smoker in the act of raking out the sooty accumulation, the wire passing through the valve into the blast-tube. You observe that the valve-hole, instead of being located where the small staple is now, is placed directly opposite the blast-tube. The arrangement for permitting the closing and opening of the valve is simply a screw cap of a suitable size. The leather is punched to receive the rim of the cap, and is glued fast. When the cap is screwed on we have a valve that works as before. If it is desired to clean the blast-tube, the cap is unscrewed. As the new arrangement of the valve adds but a trifle to the original cost of the smoker, we will furnish the smokers at the same price as before. There is only one defect in this valve. After the accumulation of soot has collected in the cap, it is sometimes difficult to unscrew it. But one with a pair of stout fingers ought to be able to loosen it. The bellows must be tightly closed, otherwise the unscrewing of the cap will loosen the valve.

This improvement greatly facilitates cleaning, as well as making a better job of it. The soot, instead of being pushed in the bellows, as in the old way, is, by the plan above, shoved out through the valve-hole.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,

EDITOR AND PUBLISHER.

MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, FEB. 1, 1887.

If, when ye do well, and suffer for it, ye take it patiently, this is acceptable with God. 1. PET. 2: 20.

The department of Circulars Received is crowded out this issue by advertisements.

The total number of new names received during the past month, exclusive of renewals, was 528; ordered out, 190. Total number up to date, 6424.

PROF. COOK'S NEW BOOK ON THE MAPLE-SUGAR INDUSTRY.

The title of the above book is, "Maple Sugar and the Sugar-bush." It will be a book of about 50 pages, profusely illustrated, and we hope to have it ready to mail by the 15th of this month. Price 40 cts. by mail, postpaid. If ordered with other goods, by express or freight, 35 cts.

THE BEE-KEEPERS' ADVANCE.

The above is the name of a new journal, or rather, perhaps, the name of the *Maine Bee-Journal*, commencing with the new year. It is now in the hands of our good friend J. B. Mason; and as he has been a good straight honest man heretofore, we suppose he will be a better one since he has become an editor. The January number is at hand, and full of good things; but if I were in friend Mason's place I don't believe I would have my price list of supplies bound together with the journal. I know there are other journals that do the same thing; but as we have, as a class, been accused of running our bee-journals solely to advertise our supply business, will it not be better to shun even the appearance of evil?

EXTENDING THE TERRITORY TO THOSE WHO ARE SOLICITING SUBSCRIPTIONS FOR GLEANINGS.

SEVERAL have asked us if they could not take names at adjoining postoffices as well as at their own, and we have decided that you may get subscriptions anywhere you choose, provided you see the parties personally, and do not, in any circular or elsewhere, make any printed announcements that you will receive subscriptions for less than \$1.00 each—our established price. The principal idea is, friends, to have GLEANINGS presented to the class of individuals who would not know any thing about it unless their attention was called to the matter by some one in their neighborhood. Our subscription-list is evidently going higher this year than it has ever done before, and we think it is principally owing to this matter of personal work for it. If you do not get the subscription, be sure to send in the name, in order that we may send the party a price list.

THE AMERICAN AGRICULTURIST.

ONE reason why we value this standard agricultural periodical is because of its numerous engravings of household and farm conveniences that appear in

every issue. As an illustration: A few days ago we were talking about an arrangement of pulleys whereby our teamster could lift the box from the wagon himself, and put it on again, having the box overhead in the tool-house, entirely out of the way. In glancing over the *Agriculturist* for February, I saw a picture of an arrangement not only very much better than the pulleys, but cheaper, and I presume that this one picture saved me much more than the price of the journal for a year. It saved a good deal of thought and study, and gave me a better machine than it is at all likely I should have got hold of without its help. The regular price of the journal is \$1.50 per year, but we can furnish it to our subscribers for \$1.25.

MR. THOMAS HORN.

AFTER considerable correspondence, Mr. Horn has finally consented to have me collect all the claims against him; and to end all controversy and long letters, he proposes to give his note for all indebtedness. These notes are to be payable in two years, but he is going to try to pay them up this season. Ten per cent is to be added for the use of the money. Now, then, write me just how much Mr. Horn is owing you; and when the amounts are ascertained to be correct, I will forward you his note. Please do not write long letters about it, if it can possibly be avoided. When we get every thing settled, Mr. Horn is to advertise again, and make the attempt to get back the reputation he has temporarily lost. We presume most of his customers will consent to receive bees or queens this season, instead of asking for the cash back again; but the note is to be held until the account is settled satisfactorily. Let us make it as easy as we can for him to get on his feet again, for you know there is joy even in heaven over every sinner that repenteth.

WHO SHALL BE GREATEST?

In the issue of the *British Bee Journal* for Jan. 6, we notice some reflections on the American people for having copied the inventions of our British friends, without giving credit, and it is stated that the one-piece section was made in England at least one season before it was made in America. No doubt this may be so, but I do not believe it will benefit any of us to spend very much time in looking it up. Let us by all means be careful to give credit whenever we get an idea from any one. With the multitudes on both sides of the water who are now contributing to our inventions and bee-literature, it may be, however, sometimes quite inconvenient to acknowledge every suggestion by which we have profited. Let us remember the Savior's words to his followers when he found them disputing among themselves as to who should be greatest. Quite frequently I find my inventions used and described, without any credit whatever to the source. Sometimes articles are copied, or portions of them, without credit. This species of plagiarism is not confined to this side of the Atlantic, however; for on page 285 of the *Bulletin d'Apiculture de la Suisse Romande*, one of our ablest French exchanges, edited by Ed. Bertrand, at Nyon, Switzerland, we read:

We are pained at times by the custom that some journals have of reproducing articles from our *Review*, without giving credit, or simply giving the name of the writer of the article, without paying any attention to the law of literary propriety, which demands that the name of the proprietor—that is to say, the name of the journal, be indicated. This is a convenient way of obtaining the work of our co-

workers. Another method consists in taking the text and changing the lines a little.

As for *myself*, I do not see that it matters very much, after all. If the public are benefited, does it make any great difference "who is the greatest"?

ARTIFICIAL COMB HONEY — SOMETHING MORE ABOUT IT.

A SHORT item appeared in the Pittsburgh *West-End Bulletin*, to the effect that there was an establishment in Pittsburgh making comb honey, etc. Our good friend W. H. Ferguson, of Bloomsdale, O., while in the above city, took the pains to follow it up. The editor of the paper declared there was no mistake about it, and gave the street and number. When our friend got there they said it was a fact, but that it was off somewhere else, up three flights of stairs, and so on. What do you think they found? Why, a man who makes cement and sealing-wax; and it happened that this worthy tradesman also put up very neat little cakes of wax for the sewing-table—just that, and nothing more. As he is said to be both honest and industrious, we give his address to the friends who may want little cakes of wax—postoffice box 155, Pittsburgh, Pa. Now, then, who comes next?

SPECIAL NOTICES.

MAPLE SYRUP.

In view of the crop soon to come, we offer the remainder of the lot mentioned on page 1002, Dec. 15th issue, at 75c per gallon; or 85c per gallon with package included to ship it in.

DISCOUNTS ON GOODS FOR THE MONTH OF FEBRUARY.

As before announced, we shall make an extra discount of 3 per cent on all goods of whatever nature, mentioned in our price list, for orders received during this month. The object is, to prevent the rush and crowd that comes a little later on.

THAT LOT OF GLASSED COMB HONEY.

In order to close this out before the new season opens, we have decided to offer it at an even 10c per lb., in lots of 10 cases; less than 10 cases, 10½c per lb. For weights of cases and further description, see page 329, April 15, 1886. If you have not the above number we will mail one on application.

FRENCH BEE-JOURNALS.

We have on hand a large lot of nearly all the standard French bee-journals published. We will mail any number, as long as they last, to all who can read them, for 3 cts. per copy. So far as possible they will come in regular order. At this rate we can not promise to select any particular number.

FRIEND MARTIN'S CHROMO.

As a general thing, it will not do for us to make editorial mention of the things offered for sale in our advertising columns. Friend Martin has, however, gotten up a chromo of such exceeding beauty that we do not feel as if it would be right to pass it by. The figures of the bees and queen stand out like life. The Chapman honey-plant is wonderfully true to nature, even to the colors. The same is true with the alsike clover and other honey-plants. Even Heddon's hive is a thing of beauty, as the chromo shows it. The idea is, to have your price list printed on the back of these cards. For convenience in this latter respect, we will furnish them here at his prices. The cost of the printing on the back side will depend on the amount of matter. The size is about that of a common postal card. One feels, in looking at this, as he does in looking at many of the seed-catalogues nowadays—the pictures are a good deal nicer, many times, than the thing itself.

WHAT KIND OF SEED SHALL WE PLANT?

SOME EXCEEDINGLY KIND WORDS FROM FRIEND GREEN, OF THE EXPERIMENT STATION, COLUMBUS, O.

FRIEND ROOT:—I am much pleased with your catalogue of seeds. Many might think, that, because your list is so short, you do not have the best to be had; but my reason for being pleased is the fact that you *have the best* and about *all the best*, varieties known to the trade, and have put the matter in such shape that even a novice can select. You have condensed a voluminous catalogue to two pages, and have left out hardly a single valuable thing; or, to use a very common figure of speech, you have given us the "cream" of the catalogues. The list is not yet quite so short as I would have made it, and I would put in a few varieties not found there; but it is near enough to my ideal to meet my hearty approval.

I know that one's success in gardening depends largely upon a good selection of varieties; and I know, also, that the majority of people do not know what the best varieties are. The ordinary seed-catalogues are so voluminous as to be confusing to all except the experienced gardener, and he is often misled by a flaming list of novelties. Having tried almost every thing, and found so few varieties that are really good, I can readily see how serious losses and vexations might come because of these bad habits that our seedsmen have fallen into. I have really taken the matter quite to heart, and have ardently desired to see a reform inaugurated. I have not blamed seedsmen, at least none in particular, for the evil has grown so gradually, and apparently in such an innocent manner, that the blame can be attached to no one alone. Furthermore, I had come to think, with many seedsmen, that a short condensed list would carry no weight, and bring but few customers. I hope, Mr. Root, that you will not hesitate to tell us the results as nearly as you may be able. If others know as well as I know that you have not only selected the best varieties, but have bought your seeds of the most reliable growers, they would not hesitate to order of you. You might have bought seeds that would not have cost you half the money, nor that much, indeed, in the case of many articles; but you have selected the best, and I earnestly hope that you will be rewarded; but I really fear that your reward will be almost wholly that which comes from having a good conscience, which every man ought to have, but he is entitled to something more also, if he is diligent.

One thing further I should be glad to see done; but if it is done at all it must be done in a convention of seedsmen. That is, to reform the nomenclature of vegetables. At present every one has his own way of writing names. One writes Early Wakefield, another puts in the Jersey, and another prefixes Very. An old English pea is called, by some, Early Philadelphia, while others, like Landreth and Henderson, prefix their own names. Thus it gets out under a dozen or more aliases. So on through the list, almost every thing having several names. If this does any one any good, I am unable to see how; and I am not ignorant of the arguments in favor of it. That it does harm, there can be no doubt; for it is a stumblingblock in the way of thousands who buy seeds. Suppose that some one concludes to give you an order, but fails to find in your list what he wants. It is altogether probable that it is there, but under another name, or, what is still worse, the same name is often used for entirely different things; and even the most careful may thus get deceived in buying. Fruit-growers have had the same trouble, but they have brought about a reform, and seedsmen ought to do the same. I can not believe that things are so disjointed in this world that it pays to *perpetuate* a wrong. Every seedsman who aids in keeping up this Babel of names is doing his customers an injustice, and I do not believe that such a course is consistent, nor in accord with business principles. It surely is not honest for a seedsman to prefix his name to a thing, or rename it in any way, and then send it out at a high price as something new, when every seedsman has it; and I do not believe that such a course pays in the long run. It is, however, done frequently, and a large share of the surplus names come in that way. I do not object to an improved sort being

called "Improved," or in some way designated, and let the improver have the credit, but we want short names, and honest names, and I hope the time may come when we shall have them.

Columbus, Ohio, Jan. 4. W. J. GREEN.

After reading the above I wrote immediately to friend Green, saying that I would gladly pay him for the time and trouble required to cross out and add in such garden vegetables as he thought advisable. I also desired him to direct me in regard to asparagus, potatoes, and a few other things omitted in our list, as given on pages four and five, issue for Jan. 1. The following comprises all the additions he has thought fit to make. The only things he has crossed out from the list as I gave it is the long blood beet, the Stone-mason cabbage, and the Trophy tomato. He does not mean to say by this that the above are not good, but that we have others so much better he thinks it advisable to drop them out. The additions are made as follows:

ASPARAGUS.

Conover's Colossal. Oz. 5c; lb. 50c.

These are said to be improvements upon this variety, but they have not been fully tested. No one will lose any thing by planting this old standard.

BEANS.

White Marrowfat. Pt. 10c; pk. \$1.00.

One of the best to use shelled, when green or ripe.

BEETS.

Lane's Improved. Oz. 5c; lb. 40c.

The best variety for stock-feeding. It showed a larger per cent of sugar at the Experiment Station than any other analyzed.

Long Red Mangel. Oz. 5c; lb. 30c.

Yields well, but not so sweet as the above.

CABBAGE.

Louisville Drumhead. Oz. 15c; lb. \$2.00

One of the most uniform and surest-heading sorts tried at the Ohio Experiment Station. It is a little later than Flat Dutch, hence may be planted later; just the kind to plant after early crops.

CARROTS.

Orange Danvers, Half-Long. Oz. 5c; lb. 60c.

Yields well, and is easy to dig. The best sort known, by all odds.

CORN (FOR TABLE USE).

Livingston's Evergreen. ½ pt. 5c; pk. \$1.00.

Earlier than the Mammoth. Excellent as a market variety, also for drying and for home use.

ONION.

Yellow Danvers. Oz. 20c; lb. \$2.50.

A standard yellow variety. The best of all to grow from seed. It makes a wonderful difference, however, how the seed is grown. Some strains will give nearly double the crop that others will.

PEAS.

Landreth's Extra Early. ½ pt. 5c; pk. \$1.50.

We consider this equal to any for the first peas of the season. The same as the First of All, First and Best, and other extra earlys. It yields its crop in a very short time. Not equal in quality to the following:

Marrowfat. ½ pt. 5c; pk. \$1.00; bu. \$3.50.

One of the most desirable and well-known late sorts.

POTATOES.

Early Ohio. Per peck, 50c, or \$1.25 per bushel.

The Experiment Station, Columbus, O., says there is nothing earlier.

Our whole crop of Early Ohio last season was sold at \$2.40 a bushel. Of course we could not offer the seed at the above prices were in not that we procured our seed of a neighbor who raises potatoes largely.

Early Pearl. Per peck, 75c, or \$2.50 per bushel.

The Experiment Station finds this about as early as the Early Ohio, and perhaps yields a little better.

Lee's Favorite. Per peck, 50c, \$1.25 per bushel.

This is a few days later than the foregoing, but yields a little better still.

Empire State. Per peck, 40c, \$1.25 per bushel.

This, the Experiment Station considers as good a late or medium late potato as any before the public. They decide that the above four varieties are the cream of the list.

KIND WORDS FROM OUR CUSTOMERS.

Box received; every thing is all right, perfectly satisfactory. A part of the articles are already in use. Wm. C. PALMER.

Old Chatbam, N. Y.

The section honey I ordered of you some time ago, received in good order; no leakage and no breakage. Wm. BITZER.

Fulton Station, W. Va., Nov. 29, 1886.

GLEANINGS has become a household fixture. The A B C is our best counselor. The "Home of the Honey-Bees" is that Mecca to which one longs to make a pilgrimage. L. F. STODDARD, M. D. Ramsay, Ill.

Accept my thanks for the favors you have shown me during this year. Your goods were satisfactory in every respect, and all arrived without the slightest injury. W. T. HORTON.

Confluence, Pa., Nov. 24, 1886.

THAT WATERBURY RUNS UP TO A MINUTE.

I have had dealings with you, and found you always to deal on the square. The Waterbury you sent me runs just as you said it would, up to a minute—the best timepiece I ever had.

Pleasant Mound, Ill.

W. G. HAYEN.

The honey arrived all right. I have sold nearly \$8.00 worth of it, clover honey, at 15 and 16½ cts; basswood, at 12½ and 14. Plenty of California honey in town at 10, section boxes at 13, for sale. The "Little Detective" is a gem. D. HOWARD.

Dover, Del., Dec. 10, 1886.

"BREAD CAST UPON THE WATERS."

I want GLEANINGS and the *British Bee Journal* another year, sure. GLEANINGS I should want, even if I took no interest in bees. I don't wish or intend to flatter, but your labors in GLEANINGS for the benefit of the world generally are appreciated by myself, and have been the means of leading me to consider the hereafter as nothing else has done. You may not feel that you are getting an immediate reward for your work, but it is "bread cast upon the waters," and it will surely return. You will find in your crown of glory many stars that in this world you will have no knowledge of.

J. E. POND, JR.

Foxboro, Norfolk Co., Mass., Dec. 10, 1886.

HOW A WOMAN CAN MAKE USE OF OUR WHEEL-BARROW.

Inclosed find \$2.00 for goods mentioned below. I am ashamed for not letting you know how nicely those goods were packed. They carried well, and we were all so well pleased with them we could not find fault if we tried to. We were pleased with every thing, from the 10-cent wrench to the wheelbarrow. That little wheelbarrow is a blessing to women. It saves many steps. We use it in the house and out of the house. I never knew before that a wheelbarrow could be made to be so useful. Of course, some would ask, "What could you do with it in the house?" Try it in taking up carpets and what not; in house-cleaning, etc. Try it in bringing vegetables from the garden. I think mine a very nice piece of furniture when brought into the kitchen, loaded with sweet corn, tomatoes, etc. With a little care there need be no litter. I never allow the chickens to roost on my wheelbarrow. It is too good a friend. If it should get broken I should have to have another right away. MRS. ANN SCAIFE.

Barboursville, Lyecoming Co., Pa., Nov. 30, 1886.

THE A B C OF BEE CULTURE.

I think I can claim, or rather begin to claim brother on bee-keeping, after the success we have had this summer. Wife and I are partners in bees as well as in every thing on the farm. Only one thing we do not agree on—I have had two A B C's and sold them both in a short time after I got them. Wife rebels, and says she is going to have one herself, as we can not keep bees without it. I had 9, spring count, all pretty good and strong. We took off 1250 lbs. of comb honey in 1-lb. sections, and 200 lbs. of strained. We increased to 23; sold 5, lost 1, and now have 17, packed away in chaff and forest-leaves, on summer stands. I think we have

one swarm that is hard to beat for brown bees. I don't like the name "black." We took from it 175 lbs. in pound sections. How is that for an A B, not yet to C, scholar? Three years ago we hardly knew a drone from a worker. We have not lost one yet in wintering. We thank the A B C book for it, with GLEANINGS to help. We could not do without your journal. I miss Our Homes every other week. I would rather have it come twice a week than twice a month.

JOHN H. KIRK.

Royalton, Mich., Dec. 24, 1886.

EXCHANGE DEPARTMENT.

WANTED.—To exchange for good horses and mules, 200 colonies of bees in Simplicity frames; also 40 acres of land adjoining the city. 20tfdb ANTHONY OPP, Helena, Phillips Co., Ark.

THOROUGHbred fowls. Brown Leghorns, S. S. Hamburgs, W. C. B. Polish, P. Rocks and Wyandottes, Bonney's, Forbes', Hawkins', Wilcox & Fultz' strains. We will sell for cash, or exchange for fdn. and beeswax. Price list free. 18-19tfdb A. H. DUFF, Creighton, Ohio.

WANTED.—To exchange, nursery stock of all kinds (evergreens a specialty), for Italian bees, tested queens; nuclei, fdn., apiary supplies, bee-plant seed. Give prices of your goods. My price list free. R. A. LEWIS, Cherokee, Iowa.

WANTED.—To exchange Gregg raspberry-plants, comb fdn., 1-lb. 1-piece sections, L. frames. For particulars, address THOMPSON BROWN, 1d Cloverdale, Ind.

WANTED.—To exchange spider-plant seeds for Plymouth Rock eggs, Conger or Hawkins strains, or offers. W. A. SANDERS, 3d Oak Bower, Hart Co., Ga.

WANTED.—To exchange extracted honey for one-piece sections. CHAS. T. GEROULD, 3d East Smithfield, Bradford Co., Pa.

WANTED.—To exchange eggs from four yards, pure-bred prize-winning Plymouth Rocks, for pure Italian queens. Eggs, \$2.00 for 13, or \$3.00 for 30. B. D. SIDWELL, 3-8db Flushing, Belmont Co., Ohio.

WANTED.—To exchange a good colony of bees in Mitchell or Simplicity frames for Rose Comb, Brown Leghorn Pullets, or Wyandotte Pullets. Nothing but thorough breed wanted. 3d DAVID LUCAS, Jewett, Harrison Co., Ohio.

WANTED.—To exchange my new catalogue of bees, queens, new section-case, for your address on a postal card. Address F. A. EATON, 3-4d Bluffton, Allen Co., Ohio.

WANTED to exchange or sell, a Given fdn. press, 3 tanks, and 1/2 doz. dipping-boards. 1tfdb J. SWALLOW, 2816 Mo. Ave., St. Louis, Mo.

WANTED.—To exchange for a self-inking printing-press (not less than 10x12-inch chase), or offers, one German-silver B-flat cornet, used but little, one novelty printing-press, 6 1/2 x 10 inch, and a lot of Simplicity bee-hives. Address 2-3d CYRUS MCQUEEN, Baltic, Ohio.

WANTED.—To exchange chaff hives or surplus crates for bees next spring. Illustrated price list on application. GEO. E. HILTON, 2-3-4-5-6d Fremont, Mich.

WANTED.—To exchange pure Italian bees for supplies or chaff hives in flat. Make offers. For particulars, address S. F. REED, 2-tfd N. Dorchester, N. H.

WANTED.—To exchange Cuthbert raspberry roots for a double-barrel 12-gauge breech-loading shot-gun, or a female ferret, or beeswax. 3-6db M. ISBELL, Norwich, N. Y.

WANTED.—To exchange Italian or Syrian queen-bees, or 3-frame nuclei of same, for a pair of Embden or Toulouse Geese, a pair of Aylesbury and Rouen ducks, Bronze and White Holland turkeys, or other fancy poultry. Address 3-4d W. P. HENDERSON, Murfreesboro, Tenn.

WANTED.—To exchange some comb and extracted honey for hives, 1-lb. sections, 4x4x1 1/4 or 2, and a few trio of Wyandottes and a few cockerels for supplies or cash. 3d L. WERNER, Edwardsville, Ill.

WANTED.—To exchange a new large pictorial family Bible, cost \$8.50, for extracted honey. 3d W. H. LAWS, Lavaca, Ark.

WANTED.—To exchange a "Taylor" Horse Power, Saws, etc. (cut furnished on application) for hive-making, and a 10-inch Root fdn. mill, tank, etc., good as new, for nice extracted honey, farm wagon, cash or offers. J. G. FITZGERALD, Brookston, Tex.

WANTED.—A sandpaper section machine (Root's make) in exchange for bees, sections, shipping-crates, or a sewing-machine. 3d F. GRANGER, Harford Mills, Cortland Co., N. Y.

AT KANSAS CITY, MO.

HONEY COLUMN.

CITY MARKETS.

BOSTON.—*Honey.*—We notice a little improvement in sales, and one-pound fancy white honey is wanted; the supply is not equal to demand; price for same, from 14@15c. No change in other kinds.

BLAKE & RIPLEY,

Feb. 11, 1887. 57 Chatham St., Boston, Mass.

KANSAS CITY.—*Honey.*—No change in quotations since our last.

Feb. 11, 1887. CLEMONS, CLOON & CO.,

Cor. Fourth and Walnut Sts., Kansas City, Mo.

NEW YORK.—*Honey.*—There is no material change in the honey-market. There is a good demand for fine white comb honey, but the demand for poorer grades is limited, with plenty of stock. We make no change in our quotations. Extracted honey in fair demand, with the exception of buckwheat.

Beeswax, a little firmer, with good demand.

Feb. 11, 1887. THURBER, WHYLAND & CO.,
Reade and Hudson Sts., New York.

ST. LOUIS.—*Honey.*—The movement of honey is very light; few orders from country, and they are very small. Stock in the city is large, and seems to be still accumulating.

White-clover honey in 1-lb. sections, dull, 11@12; same in cans, dull, 5@6; Southern honey in bbls, as to quality, 3@4; California honey, in cans, amber, 4½; sage, 5. *Beeswax*, refined, 28@30; selected yellow, 28. Dark and mixed, 21.

W. H. WESTCOTT & CO.,

108 and 110 Market St.

COLUMBUS.—*Honey.*—Demand light. Best white clover, 14@15. Extracted, 10@12½. *Beeswax*, 22@25 in a jobbing way.

EARLE CLICKINGER,

Feb. 10, 1887. 117 S. 4th St., Columbus, Ohio.

CLEVELAND.—*Honey.*—There is no material change in the market. Sales continue very slow at 13c for best white in 1-lb. sections. Dark 1-lb., dull at 10; 2-lbs., white, 11@12. Extracted, 6.

Beeswax, 25c.

A. C. KENDEL,

Feb. 10, 1887. 115 Ontario St., Cleveland, O.

CINCINNATI.—*Honey.*—There is nothing new worthy of note in the market. Demand is slow for all kinds and shapes of honey. Prices remain the same as quoted last.

Beeswax.—There is a good demand for this, which brings 20@22c for good to choice yellow on arrival.

Feb. 10, 1887.

CHAS. F. MUTH & SON,

Cincinnati, Ohio.

DETROIT.—*Honey.*—Best white comb honey in one-pound sections, 12½c; other grades, 10@11.

Beeswax, 23c.

M. H. HUNT,

Feb. 11, 1887. Bell Branch, Mich.

CHICAGO.—*Honey.*—Sellers ask from 7@10 for dark and crooked to good 1½-lb. sections; good 1-lb. sections, white, but not scraped, 10@11. Fancy white in apparent good order, and scant pound sections, 12@13. Very little sold at the outside quotations. Extracted comb honey, lifeless. No sales to quote from this week. *Beeswax*, 25.

R. A. BURNETT,

Feb. 10, 1887. 161 So. Water St., Chicago, Ill.

FOR SALE.—2000 lbs. best clover honey in Root's "raised-cover pails." One set, 30½ lbs., \$2.50; 1 set, 122 lbs., \$9.25. Boxed, they ship same as bbls.

OLIVER FOSTER, Mt. Vernon, Iowa.

FOR SALE.—1 bbl. of 550 lbs. net, and 5 kegs of 115 lbs. net each, all of which is No. 1 white-clover honey, well ripened. Will take 6½c per lb. for bbl. and 7c for kegs. Sample sent for 2-cent stamp.

R. J. BARBER, 818 E. Washington St.,

Bloomington, Ill.

FOR SALE.—4 cases of 43 lbs. each, net, of the finest white-clover honey, in 1-lb. sections. Price 12½c per lb.; has been kept in a warm room, and is in good order.

RIPENING HONEY, ETC.

SOMETHING SPECIAL IN REGARD TO RIPENING THE CAPPED HONEY IN SECTION BOXES.

ON page 476 of GLEANINGS for 1886, Dr. Miller says: "It may be objected, that the bees, thus left to fill themselves, will take just so much honey out of the sections. That is just what I like to have them do, for there are always unsealed cells around the outer margin of a section, and the more honey taken from these the better." Dr. Miller, please tell us why you consider it an advantage to have this unsealed honey taken out. I used to think the same before I learned how to properly ripen honey, for in the cool damp room where I then kept it, the honey in these unsealed cells always kept thin and getting thinner, so that by the time I crated it a section could not be turned upon its side without this thin honey dropping out and daubing every thing upon which it fell. Accordingly I learned that sections must be kept right side up all the while if I would keep every thing tidy. Of course, I could do this; but how about the merchant who bought it, and the consumer? I well remember taking a nice sample of the most snowy-white comb honey I ever produced, to a merchant. I sold my honey, too, at that time, and the first thing he did was to turn the section down flat in his hand, as his eyes looked admiringly upon it; but said gaze was only momentary, for the honey from these unsealed cells which I had been so careful to keep in place was dripping down between his fingers, which caused a feeling other than of admiration to come over him. I then gave him a lesson in handling honey, and never afterward did I see him handle honey except in an upright position. But

however well I and a few others (who know how) might succeed in avoiding this daubing, yet I knew if such a state of affairs were allowed to exist that many would become disgusted with the "dauby stuff," even if I did not, so I set to work to see if I could not remedy the matter. After studying some time on the matter without solving it, I went to see Mr. Betsinger one day; and while there I went to see his honey, which was kept in a small building, only 7 feet high, having on it a rusty tin roof. As we went into the building I remarked about the great heat inside, when he said that this was as he desired it, for this heat ripened his honey so that it was thick, and never leaked and daubed things. Putting his talk into actions he picked up a section which had been in this room a couple of weeks, and turned it over, backward and forward, without a particle of drip, while one just off the hive, treated the same way, leaked badly. I then saw what was the remedy for my trouble; for heretofore I had kept my honey in a room on the north side of my dwelling-house, on the first floor, where of course it was cool and damp. Thanking friend B. for what I had learned I came home and planned my present honey-room which I have often described in the different bee-papers.

With this I was satisfied till some two or three years ago, when we had a damp cool time for about two weeks, during which the sun did not shine at all to warm up the dark paint on the outside, in consequence of which the honey gathered dampness to an extent not pleasing to me, especially as I was now about to crate it. This set me to thinking how to remedy the matter, should another such damp time occur in the future, the result of which was the placing of an oil-stove in my honey-room,

so that now I have complete control of the temperature, and can raise or lower it at pleasure by simply turning the wicks up or down. As, when the wicks are turned low down there is an offensive smell comes from the stove, I am about to fit a tin cover over the stove on which is to be fastened a length of two-inch conductor-pipe. On this I can use other conductor-pipe with various elbows so as to retain the heat and yet carry off all the fumes from the burning kerosene, the same as smoke is carried off by a stove-pipe. In this way the honey will be constantly growing better instead of deteriorating; besides, if I wish to draw it to market on a cold or cool day there will be no danger of breaking, for a body of honey will retain heat for a long time.

A MISTAKE CORRECTED.

On page 990 of same volume of GLEANINGS, Mr. Swinson says: "I think G. M. Doolittle made the statement, . . . that Syrians and Cyprians, as a rule, produce brighter-colored queen progeny than any other race." If Mr. S. will turn to page 729 of said volume I think he will find that he made a mistake in reading. I there say, that "the queens of these two races of bees are next in constancy of color to the German queens," by which I meant that their markings were more fixed and unchangeable than any other, save the German. This has nothing to do with brightness of color, as will be seen where I apply the same "constancy" to a greater extent, to black bees. I fully agree with Mr. S., that "the best domesticated Italian queens produce the yellowest queen progeny of any race we have," yet this does not conflict with what I say about queens of the other races being "most constant in color."

Borodino, N. Y.

G. M. DOOLITTLE.

Friend D., I have been thinking of your plan of ripening honey so it would not run out, and I regard it as a matter of the greatest importance. I am very glad you have taken it up for us in the very thorough way you have in the above.

ALSIKE CLOVER—WHEN AND HOW TO SOW, ETC.

ALSO SOMETHING ABOUT RAISING BASSWOODS FROM THE SEEDS.

DEAR SIR:—Whenever one of my manuscripts is not available, dump it into the waste-basket without ceremony. Can you not let us know through GLEANINGS, at an early date, when and how to sow alsike to the best advantage, and how much seed to sow to the acre when sown alone? Also how much, when sown with timothy? Please tell us when to gather basswood-seeds, when to plant, and how to cultivate.

Denison, Iowa, Feb. 1, 1887.

Z. T. HAWK.

Friend H., we are very much obliged indeed to you for the liberty you give us with your manuscript. There has been quite a little complaint of late, because we receive articles for publication and don't publish them, return them, nor give any explanation. If the friends will take a seat in the editorial chair a while, they will perhaps see why this is one of the hardest things to do, and do promptly. We are constantly debating what to use and what not to use. Now, to add to the perplexities, the contents of each mail is liable to upset the calculations we have made. For instance, an article has

been prepared for print. Something better and later comes in, and the first one is laid aside. At other times something occurs to render it desirable to hunt up and publish something we had decided not to use. So you see a great many articles are under a weight which we designate "Awaiting Further Orders." We do not put any manuscripts in the waste-basket. Sometimes an article lies on the table a month or two until we find we are just ready to give it a place. At other times, after having held it a month or two, to see just where the best interests of our readers are running, we decide not to use it at all.—In regard to alsike: As it is just about time now to sow it, we are glad you have called attention to the matter. Sow about 4 lbs. to the acre, on any kind of grain; and if you sow it on one of the last falls of snow you can easily see how thick you are getting it. Terry's favorite time to sow red clover is about the time of our last severe frosts. Whenever we find the ground all honey-combed, as it were, by the frost, with the prospect of a thaw as soon as the sun gets up, then is the time to get in your clover. The seed rattles down in these little holes made by the frost, and the thaw covers it up with damp soil as soon as the sun shines out. Have every thing all ready, and then go at it as soon as you can see, when the right time comes. Friend Terry has his breakfast put off an hour or two, rather than miss the chances of getting in his clover-seed just right. If your ground is good, so as to make a strong growth, it will pay you well to put in a sprinkling of timothy, so as to make it stand up. This matter was pretty well discussed at the Albany Convention. In very strong ground, alsike will make such a mass of vines and stalks that it is liable to rot during much rainy weather.—Raising basswoods from the seeds, so far, has been pretty much of a failure. I have just received a catalogue from George Penney & Co., Evergreen, Door Co., Wis., advertising basswood-seeds at a dollar a pound. He also has little trees for sale, and has promised to give us an article on saving and sowing the seeds, and on the treatment of the seedlings.

HOUSE-WARMING.

PROF. COOK PLEADS FOR A FURNACE, AND WOOD FOR FUEL.

I MOST heartily agree with our friends Terry and the Editor, in their position on the tobacco question. How irrational and incomprehensible, that men will, in the face of the known physical evils that attend the use of tobacco, the disgusting character of the habit, which would surely nauseate any one except that we see it from youth up, the moral obliquity, and disregard of others' comfort which its use engenders; and the worse than useless expense which goes with the habit; that any one will suffer himself to become its slave! The explanation must come with the fact that children—mere nurslings—adopt the pernicious practice ere reason and judgment are sufficiently matured to guide and control. So much the more need that we who are

parents spare no effort, either of precept or example, to hold our children, that we may influence them aright in this most susceptible period. How thankful we all ought to be, that GLEANINGS has taken the stand it has on this question! What a power for good it would be, if all our editors would join in the same blessed undertaking!

I am also one with our friends in the thought that home should be made the most delightful of all places. Only last night, wife remarked: "There are two things we will use most liberally—light and fuel. We can not afford to stint in genial warmth, or the pleasant cheer which a well-lighted room helps so materially to diffuse through the home." Wife is right. It is a wiser economy to burn a little more oil and wood, and keep the children at home, than to lose their company as they go elsewhere to burn tobacco. Why, Mr. Editor, just once fill a home with loving self-sacrifice; have ever in reach in the pleasantest room of the house—the living-room—such papers as GLEANINGS, the *Youth's Companion*, etc., and good books; have the house warm and bright these winter evenings, and we shall find it very easy to hold the dear children. Yes, this costs something, but less of both money and worry than does the street-corner, the cigar, the saloon, and, last in this awful sequence of events, the way that leadeth down to hell.

But I must differ with both our friends as to the method of heating our houses. I was brought up in the warmth and glare of the old fireplace, with its huge back-log of hickory, the ample fore-stick, and open work of crossing timbers all aglow with the leaping, crackling flames. I have used wood-stoves for years. I have used the hard-coal stove, lauded by friend Terry; I now have my office, laboratories, and lecture-room heated by steam, which you, Mr. Editor, praise as the best thing, while our present home is heated by the furnace, which you both decry, but which, in the judgment of all at our house, is by far the best way to heat our dwellings. I fear, Mr. Editor, some may be misled by what you have said—indeed, I know of one reader of GLEANINGS who is now proposing, the coming summer, to remove stoves and replace them with a furnace. He is a bee-keeper, and keeps his bees in his cellar. Yet I think he is wise, and I would not have him or any other falter in such a wise intention.

Let me briefly state my reasons for this conclusion. I think they will commend themselves to any interested person:

Steam heat is mainly objectionable in that it heats the air already in the house, and in no way effects to change it. Thus our rooms are apt to be ill ventilated, and colds and headache are the result. Again, the coils are usually not attractive, and are in the way. Once more: If the house is to be shut up, and through neglect or carelessness the steam is not thoroughly shut off, and the water all drained off, then there is liability to have bursting pipes and no end of trouble. It is also more expensive to secure a little quick heat in summer, spring, or autumn, to temper the chill of a cold morning with steam. I have a brother-in-law whose house is heated by hot-water circulation in pipes. I think the above objections all hold to this method of heating.

I object to the coal-stove heating—I mean wife and I—because it heats only a part of the house,

is a dirty thing at best—even the hard-coal dust is very pervasive and annoying, is in the way, is apt to be out of the way in cold days of summer, and is hard to start when just a little heat is desired. While the coal-stove is a little better than the steam for ventilation, it is not conducive to good ventilation. True, it draws a little of the air from the room, but in the main it heats only over and over the vitiated air, which, with these stoves, is usually retained in the rooms to be breathed again and again, thus engendering disease and enfeebled strength.

Now for the furnace. It is in the cellar, and all dust and are dirt avoided. The pleasant living-rooms are not cumbered with ugly stoves or coils. The husband can arrange the fires, and so the wife is saved to the utmost. Best of all, the heated air is drawn right from outdoors; and as it can not enter the rooms unless just so much air passes out, there is a constant exchange of air, and so our rooms are constantly well ventilated. With no trouble, every room in the house can be heated, or by the push of a lever any can be kept cool. A stick or two of wood in the furnace, on a cool morning, just removes the chill of the whole house and makes a happy household. We have had our furnace for over twelve years, and it has heated our house perfectly, has given the most perfect satisfaction, has never been out of order, and we scarcely ever go to visit our friends, where stove or other heat is used, but that we join in praise of the blessed furnace.

In arranging for a furnace, the room to contain it should be large—ours will hold eight cords of three or four feet wood, and this room should be entirely separated by a brick or stone wall from the remainder of the cellar. Thus we can keep our vegetable-cellar just as cool as though we had no furnace; and still, by simply opening a door we can surely prevent freezing in case of very severe weather. The cold-air shaft should open toward the prevailing winds—west at this place—for it opens east the strong west winds that rush around the house so suck the air as to reverse the current of hot air, and it is too expensive to heat all outdoors. But with an east opening, all will work well, even with a heavy west wind, by opening the cold-air flue into the cellar, and closing the outer opening. Yet I prefer to always take the air from outdoors. We have our chimney in three divisions—the center division carries off the smoke, and the whole chimney is kept warm. Each room is connected, by means of a register and a close pipe, with the outer divisions of this chimney. We see, then, that the ventilation is perfect. We start the fire, which heats the air fresh from outside, which passes to our rooms. This rises and pushes the cold air down. At the same time the heated chimney causes the air in it to rise, and this is replaced by the colder air from our rooms passing out. I can not see how we could have more perfect ventilation. Good ventilation means good health and long life.

We keep three rooms on the first floor, two large halls, and our children's two rooms above, heated all the time, and a third chamber when needed, and it costs us \$40.00 a year. At night I fill the furnace, close the dampers and shut the registers, except in the dining-room and sitting-room—we have no "parlor" at our house—and when I get up in the morning these rooms are warm and com-

fortable; and when I call the household, two hours later, the whole house is warmed. As I said before, we think it economy to keep our whole house as warm and cosy as possible. If we can make this the most delightful place in the world to our children, we shall have solved the problem of their habits in a most agreeable manner. Now, Mr. Editor, I am rejoicing in the hope of a visit from both you and friend Terry this spring; and if this article does not convert you both, I believe a personal examination on the spot will. A. J. Cook.

Agricultural College, Mich.

I am converted already, friend Cook; but I want to add, that steam is used quite extensively for warming a current of air brought in from outdoors, exactly as you do. We have outdoor pipes which bring in the fresh air, and pass it around the coil of steam-pipes; and just the air, and not the ungainly-looking coils you speak of, passes into the room above, as does the heat from your furnace. We have used furnaces on the plan you mention, for a good many years, but my objection is the *expense* of warming up this outer air, especially when the temperature is below zero. It takes a heap of coal or wood either to warm a large building in that way. I greatly prefer a wood-burning furnace; but in our locality it is much more expensive than soft coal, although I believe with you I would willingly pay the extra expense to get rid of the dust and smoke from any kind of coal. Our new factory is warmed by still another device. A blower run by machinery sends a blast of air (taken from outdoors) through an arrangement something like a common steam-boiler, only the steam passes through the flues, while the blast of air circulates around them. With suitable pipes we can send the hot air into any room, and it warms it very quickly.—When Dr. Miller was here he took me to task because I assumed so many responsibilities, and did so much choring about, for others. Now, if I understand it, a large part of your strength, perhaps both of mind and body, is consumed in building fires, pumping water, and taking care of the horse and cow, etc. As you get up two hours before the rest of the family, I conclude you have this two hours of hard work, down cellar and upstairs, as a regular routine each morning. If you had steam in your household, it might do every bit of this, if you except making friends with the domestic animals. Your wife could have hot or cold water taken from the well or cistern, by turning a single valve, and it has sometimes seemed to me as if the steam rejoiced in being permitted to do such service. I know all about the recreation these duties give you, but I don't believe it is good for me to be obliged to have *too much* exercise, day after day, whether I feel like it or not. Very likely, Bertie is beginning to ease his papa a little in these every-day duties, just as Ernest is now relieving me. I presume your wood-burning furnace will be most feasible for the greater part of the readers of GLEANINGS, and friend Terry's arrangement is not so very much different from it, after all. In many homes, perhaps his plan would be the best.

OUR P. BENSON LETTER.

ROOLS OF HOW TO SWARM BEES.—KONTINYUDE.

IN mi last discoarse I left you dun up in a overcoat & three (3) vales & the fokes a makin a outrajis noise. If the racket has bin kep a goin lively, it has fetcht the bees down by this time, and by this time you ar pirty warm.

The bees will be pirty shure to settel on a sour appel tree, but moar likely thay will settel onto a oke tree, pirty well up. Git a ladder & set agen the oke tree & tell the fokes to stop thair outrajis racket. Klime up to whair the swarm is hangin on a lim of the tree & shake them down onto a sheet whitch you hed plaist the sheet under the hive, & as kwick as you shake them off of the lim hurry down sose to git them in the hive. By the time you git ½ way down the tree, sumbuddy will holler "The bees is goin back on the lim," but you needent pay enny at10shun to it; klime down & see for yureself. Then you ken klime up agen & shake them off as bet. Repeat this a phue times and it will inkrease your

PROF. BENSON TAKING DOWN A SWARM.

temperreightyure. Then you ken git a saugh and saugh off the lim & thay will lite onto a appel tree whair you ken shaik them down & swarm them into the hive. By this time you will be warm. The bee is a nativ of a warm climait and likes to hev things warm. Keep on yure overcoat & things till sundown sose yule be reddi if they cum out agen. It will save the trubbel of warmin up agen. Besides you mite ketch coald if you taik them off too suddent.

If the hive is shaded poot it out whair the sun ken shine on it all day long. This will maik them shure to stay bekoz thay will see its a good warm place for winter. In a phue days, move the bees to the place whair you want them to stay. It woont do to move them the 1st day or 2 till they hev lernd to reckognize thair hive, and then thay will find it whairever you poot it.

Drive staiks in the ground 3 feet hi to set the hive onto the staiks, soze the wurms will fall & braik thair nex hwen thay cum out of the hive for exersighs. Besides, the moth miller, whitch gits into the hives and eats up the yung bees, woont hev so good a chants to find it if its up hi.

P. BENSON, A. B. S.

(Whitch is Apiculturistical Beekeepin Sighentist.)

BOOK AGENTS AND THEIR BUSINESS.

GOOD ADVICE FROM DR. MILLER.

WHILE the subject of book agents is up, allow me to refer to another phase. Among book agents, as in all other callings, there are good and bad people. For the benefit of two classes I want to speak. First, for the benefit of any readers of GLEANINGS who are good people, and who are book agents; second, for the benefit of any upon whom book agents, good or bad, may happen to call. I will give you an illustration of what sometimes happens.

A book agent of pleasing address, and who desires to do good by selling a good book, comes to my house and rings. The lady of the house, engaged at some occupation which she can with difficulty leave, possibly some mystery of cookery, at a critical moment when a few minutes' absence may bring disaster, stops and cleans up her hands, and, like a true daughter of Eve, looks a little to her general appearance, then goes to the door, and admits the stranger.

"Is the gentleman at home?" or if, as may be the case, he has learned my name, "Is Dr. Miller at home?"

Not knowing what may be the business in hand, she comes to me, where I am very busily engaged, perhaps with a hive open. Closing up as speedily as possible, I get myself a little in shape, go into the house, and greet the stranger, wondering whether it may be some old friend whom I do not recognize, and a little fearing it may be a book agent or an insurance agent. He commences, perhaps, by saying, "What a fine view you have from here! Really, I didn't know such a hilly country could be found in this part of the State."

"Yes, this is one of the least prairie-like parts of the State," I reply, in a manner equally pleasant with his own, at the same time inwardly denouncing myself for being a little hypocritical in speaking so pleasantly when I am really feeling cross at the interruption, for by this time I begin to feel sure his visit is not to be a profitable one for me. For some time a conversation is carried on by him, my replies becoming more and more in the form of monosyllables until finally he introduces the object of his visit. Failing in his effort, he goes away with a feeling of disappointment, possibly with a feeling of pity for me that I did not get the full benefit of the book or other article he wished to sell me, never dreaming, perhaps, that he has been doing me a serious wrong in making such demands on my time and patience. Now, good people, if you must have an agency for a book or a broom-holder, don't—I was going to say *steal*, but perhaps I had better soften it a little by saying don't *take* the time of others in that way. Make known your business at once. If Mrs. Jones comes to the door, don't ask her to send for Mr. Jones. Consult other people's convenience as well as your own. You have no right to impose on their courtesy by taking time that they would not willingly give if they knew your errand. To those who have calls from agents, I would say, the chances are so many that you will have to pay more for articles thus purchased than you would have to pay for them elsewhere, that in general you may do well to refuse to buy in all cases. Possibly one time in ten or twenty there might be a case where it would be well to buy; but if you allow yourself

to buy in this one case you will be likely to overbalance it by buying at a loss in two other cases, so the safe plan is to refuse all. Learn to say pleasantly, but very firmly, that in no case can you be induced to purchase. The agent will say, that if you do not purchase, you can at least look. Tell him just as plainly as before, that it is not worth while even to take the time to look. There is much in the positive but courteous manner; and the agent, thus good-naturedly repulsed, will go away much better satisfied with himself and with you than if you had wasted a half-hour by parleying.

To the young people who almost all, at some time, think of trying this sort of business, my advice is, "Don't." That's the general rule. There are exceptions. In a sparsely settled region where stores are not easy of access, even a packpeddler may be welcomed. But in towns or villages, or in their vicinity, there is no need of agents in general. There may be an exception, in the case of an article that the purchaser must try at his own home, the agent showing its use, or of some article which is never kept in stores.

Please don't think that I have no feeling of kindness for agents. In many cases they are impelled by good motives, and are really to be pitied. In my college days I was fortunately so poor as to be obliged to work my own way. One vacation I undertook the business of a map agent. I was about as forlorn and homesick a mortal as you could desire. I made little or nothing at the business, and was probably a nuisance to many, and of little use to any, for the maps were hardly worth the price, even if the profit did hardly pay expenses. When clothes-wringers first came out, I took an agency and sold a number at a fair profit, doing a good thing for the people and myself, but I went only a few miles from home, and in no case, if I remember rightly, did I sell to any except acquaintances. This was one of those cases where an agent was necessary to show the people at their own homes how to use the wringer.

Marengo, Ill.

C. C. MILLER.

Friend M., in the above article you strike at the real trouble in this matter of book agents, and I confess it never occurred to me before. It is this: They from the outset—at least a great many of them, and, in fact, all of them that are objectionable—pretend to be something they are not. If every book agent, when he comes near your premises, would hold out his book, and say, "Sir, I am a book agent; have you a few moments to spare to talk with me?" that would end all the trouble. Not long ago a gentleman who might have been, judging from his appearance, some distinguished statesman, desired to see me individually; in fact, he would not tell his business to any of the clerks. He put out his hand, took off his hat, and expressed great pleasure in being able to take A. I. Root, of whom he had heard so much, by the hand. Then he discoursed eloquently about the growth of our business, and giving employment to so many people, etc. When I had talked as long as I could afford to, I suggested getting to business. This man was a book agent. He left his package near the door, so that I might not suspect he had something to sell. Now, I was obliged to be rude with this man, and I confess I became exceedingly vexed when

he insisted that I should look over the pages of his book, and listen to his set speeches. Any business that will not succeed when a man announces at the outset just what his calling is, should be regarded with suspicion.

FOUL BROOD.

THE DIFFERENT METHODS OF CURE CAREFULLY CONSIDERED.

IN my article in GLEANINGS of Jan. 1 I detailed my experience with foul brood. In this I wish to present the methods I would recommend for its cure. Before doing so, a few words of comment on the various remedies may not be out of place.

First. Spraying or fumigating with salicylic acid. Neither of these methods is to be relied on.

Second. Muth's plan of removing combs, putting the bees on full sheets of foundation in a clean hive, and then feeding salicylated syrup. This is a good method; and if carefully and thoroughly carried out it will always be successful. The principal objections to it are, that salicylic acid is troublesome to use, as well as somewhat expensive, and that it is impractical to feed during a yield of honey.

Third. The Jones, or starvation plan. I used this plan extensively, because it was quick and simple, dispensing with the fuss and bother of spraying or feeding. Although generally successful, I would not recommend it. In the first place, it is a very expensive plan. The starving is a terrible tax on the vitality of the bees, and especially of the queen. I have had a number of fine queens ruined in this way. No colony seems to work with any energy for some time after being released, while they dwindle away with unusual rapidity. This is a loss, at whatever season the cure is attempted. If during or just before a honey-flow, the loss of honey may amount to more than the value of the colony. If no honey is coming in they must be fed to support and build them up. At such a time, starving is unnecessary, as the feeding of medicated food is a complete cure without the cruelty and loss incurred in starving them. Moreover, starvation is not always to be relied on, especially during a heavy honey-flow, or when they are hived on empty combs. Unless great care is taken to have all the bees gorge themselves to the utmost with honey—a very difficult thing at some times, and especially with some bees—and they are then starved to the last extremity, some of the honey will remain in their sacks. This honey, unless measures are taken to prevent it, is liable to be stored in the brood combs until used for brood-rearing, thus starting the disease anew. By feeding the bees medicated food during their confinement, this, as well as the other evils of the method, are obviated, as the feed, mixing with the infected honey in their sacks, renders it harmless—but then it is the "starvation plan" no longer.

Fourth. The Cheshire plan of feeding phenol (carbolic acid) without removing the combs. This will undoubtedly succeed when all the conditions are favorable, but I can not recommend it as practical, though a more extended experience might change my opinion. The amateur can afford to experiment and run risks. He who has only a few colonies of bees can usually spare the time required to cure by feeding and similar manipulations; and if he loses a large part of his honey-crop in doing

so, he does not notice it very much. But to the man who makes a business of bee-keeping, whose bread and butter depends on it, it is a matter of considerable importance whether the cure is accomplished in one day, or whether it is spread out over several months, increasing the chances of spreading the disease many times, and consuming much valuable time. He can not afford uncertainty, nor can he afford to lose his honey-crop.

In seeking for a certain, speedy, and inexpensive cure, I observed that, during a heavy honey-flow, the progress of the disease was measurably abated, except in the worst cases, and some colonies cured themselves. Why was this? I decided that the disease was generally conveyed and propagated through the medium of honey. When honey is plentiful, the larvæ, instead of being fed on honey which has been in the hive for some time, and thus become infected, have their food prepared from honey fresh from the fields, with which every bee is gorged. The best time to attempt a cure is when nature is inclined to assist.

I noticed, too, that "starved" bees, released on combs, frequently had the disease again; those hived on full sheets of foundation, very seldom; while none of those compelled to build their own combs showed any trace of it. This convinced me that any plan which would prevent brood-rearing for several days, at the same time using up the infected honey from the old hive, would render the bees incapable of transmitting the disease. The most practical way in most cases is to compel the bees to build a new set of combs.

HOW TO CURE FOUL BROOD.

As soon as you discover the presence of foul brood in your apiary, make up your mind that you have to deal with an enemy that will require your utmost care and vigilance to subdue. Remember that prevention is better than cure. Foul brood is probably more often spread by careless handling than in any other way, so be careful that, in your efforts to cure, you do not spread the disease.

To start with, get a supply of carbolic acid. You will do best to buy it in the original bottles, holding a pound each, which should not cost you over 75 cents. If you buy a less quantity it will be more or less diluted with water to keep it liquefied. Find out what per cent of water there is in it, so that you may know what you are doing. There is a great difference in the quality of the acid. I have used that from several different manufacturers, Graesser's proving the best. Make a 3% solution of the acid. If you have not the apparatus for accurate measurements, take a tall bottle and measure into it carefully 100 spoonfuls of water, marking with a file the height which it reaches. To make a 3% solution, put in three spoonfuls of acid and fill up with water to the mark. This solution is for washing your hands, implements, etc., after any work with diseased colonies. You will do well to have a special smoker, knife, brush, etc., to be used only with affected colonies. Remember, the disease is very contagious, and may readily be carried on the hands or any implement. Just how far this contagiousness goes I can not say; but to be on the safe side I would disinfect every thing that has come in contact with any part of an infected hive before using it in other work.

The best methods of cure will vary according to the season. The best time is when honey is coming in freely. At such a time, prepare a hive as follows:

Contract the brood-chamber to four or five Langstroth frames, according to the size of the colony. Have in these frames nothing but starters of foundation, $\frac{1}{2}$ inch wide. Place over the brood-chamber a queen-excluding honey-board, and above it room for surplus, according to the needs of the colony. The sections may contain full sheets of foundation. Put this hive on the stand of the colony to be cured, removing the ashes, sand, or whatever you have in front of the entrance, replacing with fresh. Shake or brush the bees down in front of the hive and run them in. In all this, disturb the bees as little as possible, so that they may not fill themselves with honey. The philosophy of the method is, that the bees are compelled to build considerable comb before they can rear any brood. This consumes what honey they have in their sacks in wax-making. If any remains unused it goes into the boxes instead of being stored in the brood-chamber, and thus becomes harmless. In very bad cases it may be well to hive the bees in an empty box or old hive for two or three days, then shake them out and melt up the comb they have made, into beeswax.

If honey is scarce in the fields, put the bees in an ordinary-sized brood-chamber, on full sheets of foundation, and feed them phenolated syrup until they are self-supporting. To prepare this, take honey, or syrup of the same consistency, and add one-sixth of one per cent of carbolic acid. Thin this down, as required, for feeding.

The combs from which the bees were shaken may be tied up over other colonies which have the disease. Put them three or four stories high. As soon as there are bees enough, shake the queen and a good-sized colony of bees into a wire-cloth box, and, after one or two days' confinement in a dark place, hive them on a new stand. Ten days after the queen is removed, give the old colony a queen-cell or young queen, as those they raise may not hatch. In ten days more, treat them as first described. Extract the honey, boil it, and make the combs into wax. Be very sure to disinfect thoroughly every thing that has been used in doing this; and be sure, too, that no bee gets a taste of the honey in all your operations. There is so much danger in trying to do any thing with the combs, that, unless you have many, you had better burn them up.

The hives may be disinfected by thorough boiling. Scalding will not answer. A little lye or wood ashes in the water will take the propolis off clean. If you have not facilities for boiling hives, add 5% of carbolic acid to strong soapsuds, and scrub the hives well with the mixture, rinsing afterward. I think I would rather depend on this, if thoroughly done, than on boiling alone.

In conclusion, I would say that, if you are careful, prompt, and thorough, you can cure foul brood. If you are not so—and most people, I believe, are not sufficiently so until they have had some costly experience—you had better not try it, unless you have considerable at stake. Indeed, in any case, if you have only a few cases—say not over 5% of your apiary—and are sure there are no more in yours or your neighbor's apiaries, I should advise you to destroy them—bees, hives, and combs, if you can do so without handling them. If you are obliged to handle them, you might as well cure them.

J. A. GREEN.

Dayton, Ill., Jan. 10, 1887.

Friend G., I believe you have carefully

covered the ground, and, as far as our experience goes, we can agree with all that you have said. In fact, it seems that we have practiced the same, or very nearly the same, method of cure which you consider most effective. Come to remember, in a private letter you gave us a few suggestions at the time we were battling with the disease. After receiving said letter we abandoned starving the bees, and, instead, put them into clean hives where they were compelled to build combs, or, rather, work out foundation. However, we gave frames with full sheets of foundation, and all colonies so treated were cured. Perhaps in the advanced stages of the disease, starters only would be preferable. We did not use carbolic acid, as you recommended, though we exercised extreme caution, even burning a tool that had by accident received a possible taint of the disease. Your statement, that starvation weakens a colony, is very true, as we are satisfied from repeated experiments. In regard to cleansing the hives, we have, as you know, used steam, and hives so disinfected have not as yet given us any trouble.

DRONE COMB.

FRIEND DADANT GIVES US SOME VALUABLE IDEAS IN REGARD TO IT.

THE above subject, treated by Mr. Hutchinson, in GLEANINGS, Nov. 15, drew my attention, and incites me to redress some, to my mind, false notions accepted as truths by about every bee-keeper.

1. A swarm, hived on empty frames, always begins its construction by worker cells.
2. If the queen of a swarm is removed, or dies, while the bees are building, all the combs, made during her absence, will consist of drone cells.
3. If the queen of a swarm is very prolific, very little drone comb will generally be made by her bees.
4. If, on the contrary, from old age, or from some other cause, the fecundity of the queen is deficient, her bees will fill the hive with a quantity of drone comb.

I am persuaded that every true bee-keeper will admit the above, premises; from which I draw the inference, not only that the presence of the queen in the hive compels the bees to make worker cells, but that they rush into the building of their preferred (store) cells as soon as the queen ceases to control their work; for, a very prolific queen, having to wait for cells, is all the time watching the work of her bees; while a slow-laying queen is soon left behind. Then her workers, acting without control, hasten to build drone comb, which would be more appropriately named store comb. Such actions prove, without possible contest, that there are two opposite preferences during the building of comb, the preference of the workers for store combs—a preference which bows before the desire for worker cells manifested by the queen, who exercises her sovereign authority in this one circumstance only.

The deficient prolificness of a queen is not the only cause which allows the bees to build too many store-cells; for we meet with swarms which, although having very prolific queens, have constructed a large amount of drone comb. Such a fact

is not of rare occurrence, and can be easily explained. We have put a heavy swarm in an empty hive, whose frames can admit 100,000 worker-cells. The bees hasten to build combs at the rate of 3500 cells daily; the queen follows them, laying in every cell as soon as half constructed. Such going, hand in hand, of the queen with the workers, lasts 15 days; then the flowers, becoming scarce, the building ceases, together with the laying of the queen. Six days after this interruption, the hatching of eggs, laid on the first day, begins, leaving, every day, 3500 cells empty. If this dearth of nectar continues for 15 days more, then 40,000 cells, of the 50,000 which had received eggs, are ready to be filled again. If, at that time, some other flowers have begun to give honey, the laying of the queen is resumed, together with the building of comb. But the queen is no more near the builders, to require worker cells; she is far away, laying in the first comb. Then the bees, no longer restrained by her presence on the spot, fill, with store-combs, the half of the hive, which, so far, had remained empty. Had the queen rejoined her bees after a while, the building of worker comb would have been resumed, and the hive would show a patch of store-cells in the middle of its worker combs.

Every bee-keeper has noticed such irregular building of combs; but nobody, so far, has tried to explain it. In fact, it is inexplicable by any theory other than the one which I have just developed. We are accustomed to endow bees with so much knowledge that this theory could not come to the mind of our best authorities in apiculture, on account of its extreme simplicity.

The facts related above show that the circumstances of the building of worker and drone comb vary *ad infinitum*; and it is to such varied conditions of building that the diversity of results, as described by Miss Cora Major, page 716, is due, and not, as Mr. Hutchinson supposes, to the foresight of bees, who, "knowing that their queens are old, have in mind the superseding of them, and think that drones must be provided for the fecundation of the young queens."

In the experiment of Miss Cora, 10 swarms had built very little or no drone comb; 5 had from one-fifth to one-half of the space given, filled with it. If we admit the idea of Mr. Hutchinson, we have to acknowledge that the bees of these five colonies were very far-sighted; for, the life of a queen lasting, on an average, about 36 months, the 15 swarms had less than one queen to supersede every two months. Then the workers, of some of these five colonies, prepared comb, to raise drones, 8 or 10 months previous to the death of their queens; while some of the 10 colonies, which did not prepare any drone combs, or which prepared only a few square inches, could repent of not having prepared themselves for the emergency, if, for some unexpected cause, their queen had to be replaced.

I had just written the above when I saw, in *GLEANINGS* for January 1, page 51, the relation of an experiment, made by Mr. J. A. Buchanan, which confirms my theory.

A large swarm had been hived on 10 Langstroth empty frames. Seven days after, the hive was entirely filled with $\frac{3}{4}$ worker and $\frac{1}{4}$ store cells. Mr. Buchanan cut out the store, or drone combs, which were rebuilt by the bees, with worker and a little drone comb. These last having been removed also, the bees rebuilt them also with worker comb. Every

bee-keeper has noticed, that, when drone comb is removed from the hives, the bees, in nearly every instance, build nothing but drone comb in its place. Then why did the bees of Mr. Buchanan act differently? My theory explains this fact, not only easily but conclusively. A ten-frame Langstroth hive has room for about 80,000 worker cells. Then the bees of this swarm, having filled the hive in seven days, had built about 11,600 cells every day, on an average. Of course, the queen was unable to fill so many cells as soon as they were constructed. But such a fast building is always caused by a heavy crop of honey. This honey, stored in the cells as soon as they were built, had helped the queen to follow the builders with her laying during the four first days.

If we suppose that the queen had laid 3500 eggs daily, there were, on the fourth day, 3500 hatched grubs to nurse. But this nursing, consuming honey and pollen, increased the number of empty cells, in which the queen could lay. Besides the ripening, or evaporating, of the honey gathered during the three first days, and the subsequent transporting of this condensed honey in the upper cells, offered also to the queen a quantity of empty cells, that she was no longer able to fill, without ceasing her control on the builders, which, unrestrained, began to prepare drone-cells. The removal of those store-combs, by Mr. Buchanan, three days later, delayed the workers and allowed the queen to regain her place among the builders, and to obtain the building of worker-cells. But the queen was soon again left behind, and the building of drone comb was resumed. The second cutting of drone comb, by Mr. Buchanan, disturbed again the bees, which were soon overtaken by the queen, and compelled to finish their building with worker-cells. Had Mr. Buchanan postponed, for 21 days, the removing of the store-combs, the queen, having daily at her disposal about 3500 cells from which the first-laid eggs had emerged, the workers would have replaced with drone-cells all the combs removed.

From this interesting experiment of Mr. Buchanan, coupled with my theory, we can draw the inference that, if we desire to have the drone comb of a hive replaced with worker comb by the bees, we ought to deprive the queen of all the empty cells before introducing our empty frames, remembering that, if the queen had cells in which she can lay far from the builders, the bees will construct store-cells exclusively.

CHAS. DADANT.

Hamilton, Ill.

Friend D., your idea is ingenious and wonderful; but I confess I shall want to think about it and watch it a little before I am ready to accept it. So far as I have observed, I have not been able to learn that the queens control or "boss" any thing about the hive. I do know this, however: After she is taken away, the bees, with very few exceptions, change from worker to drone comb. I have seen one or two exceptions, nevertheless, where bees built worker comb at the same time they were building queen-cells. It used to be said, that the queen led out the swarm; but in most cases it has seemed to me that the bees led out, and the queen followed along with the rest. I should think it quite likely, that, if the queen were in one part of a large hive while the comb-builders were in any other part, they might build drone or store combs. If this be true,

I should expect the bees to fill surplus-boxes with drone or store comb, instead of worker-cells, especially if the queen were absolutely compelled to remain in the brood-chamber by means of the perforated zinc honey-boards. I believe others besides friend Hutchinson suggested, years ago, that the bees build drone comb whenever they are thinking of swarming, or rearing another queen; therefore if their queen seems to be failing or defective they would instinctively build drone-cells, and seem anxious to have the queen fill them with eggs. This whole matter is deep water, and it serves to show us how little we *do* know in regard to the workings of these wonderful insects, if nothing more.

EATON'S SECTION-CASE.

WHAT TO DO WITH HALF-FILLED SECTIONS LEFT OVER FROM THE PREVIOUS SEASON.

THE cut below represents my new section-case; not so new, either, as I have used it for the past four years on more than one hundred colonies of bees in obtaining comb honey. Success depends largely on the style of hive used, a thorough knowledge of the time, and how to manage; and last, but not least, the manner of arranging the sections on the hive in order that the bees may have perfectly free access to them.

A SECTION-CASE FOR TIERING UP.

There are a good many little points to be got at to make a receptacle for sections on a hive, the most convenient for the bees and the apiarist. This is what I have aimed at in my case; and I like it much better than other cases I have used. There are some who use and prefer single-tier wide frames. Well, with wide frames we have to have an outer case to hold the wide frames, besides all those wide frames to take care of out of season. You see, by the above cut, that all I have is the outer case and the bottom-bars of the wide frames combined; the sections sit on the slats the same as they do in the wide frames. This keeps them clean on the bottom, the same as with a wide frame. With the latter you can use separators, which is difficult to do with most of the popular section-cases in use. I have no use for separators. By using full sheets of foundation in sections seven to the foot, and leveling the hive with a spirit-level sidewise, and tipping it forward slightly, you will have ninety-nine out of one hun-

dred nice straight sections that you can crate. But if you use wider sections you will have to use separators. By using sections (7 to the foot) without separators they will weigh as near a pound as the 1½-inch will with separators. With my case you can use separators if desired, as well as without, by slipping a half-inch strip of tin in between the two end rows of sections, so as to hold the separators up from going down between the slats. Then as you set in a row of sections, set a tin separator in.

Now, then, there is another point, although a minor one: The sections set compactly over the brood-nest. There are no wooden partitions between each row. There is but one bee-space between the bottom of the slats and the brood-frames, the slats forming a sort of skeleton honey-board. The case is a bee-space deeper than the sections, thereby admitting of tiering up to any desired height. The slats make the case solid and substantial. If such a case were nailed up solid, and the sections fitted in it, the first sections would be very difficult to remove; and as there are slats under the sections you could not invert it and drive them out. I found that, by such a practice late in the fall, with other cases, when the weather was cold, it loosened and broke out comb, so I provided a hinged side which opens out, thereby loosening all at once. If you wish to remove any sections on the hive you can open the side and remove sections without taking it from the hive. I use an eight-frame Langstroth hive for comb honey, and make my section-cases of the same material and size of the hive. The crates are painted, and when set on the hive they form part of the same. When I tier up, the cover raises and sits on the case the same as on the hive. You see such a case protects the sections the same as the main part of the hive. It is not patented. You are free to use it, if you see any points of excellence in it. But it would be difficult to make one from the above cut, without having a sample, as there are important points of construction that do not show.

HOW TO GET BEES TO COMMENCE WORK IN SECTIONS, AND USE PARTLY FILLED ONES.

I am stimulated to give my plan, from the fact that, when describing it at our convention at Columbus, no less a person than Dr. Besse said it was worth his entire trip to the convention; so it may be of use to others, and especially to Bro. Dibbern, who, in the *American Bee Journal* for 1886, page 774, recommends, after extracting, to cut out the comb, render the wax, and burn the sections. Well, of all things such a plan would be too extravagant for me. There is nothing new about using half-filled sections of the previous year, to induce bees to go to work in the sections; but it is generally recommended to extract the honey, then place a few of them in the center of the first tier of sections; in this way you get the center of your case filled first, the end rows being left until the last, and sometimes they are very slow to finish them. My way is, not to extract the honey at all. It is too tedious; besides, it is of more value in the comb than out; but when you are ready to put on your first sections, uncap some of these half-filled sections, and fill in the two end rows of your case. Now fill the two center rows with foundation. These freshly uncapped sections will attract the bees to work in the ends of your case at once, and they will not leave the center alone very long. If this is done just as the honey-flow starts, at the proper time they will finish the entire case about the same time. These half-

filled sections will be finished out with new honey, and be recapped nice and white. You will be surprised to see in how short a time you will have nice new honey for the market. Now, some will say that that old honey in there will be inferior, and will be noticed by my customers; but such has not been my experience. If there are any uncapped cells that have granulated, the bees will work it over, taking out the granules. I have from 1500 to 2000 of these unfinished sections, left over from the previous year, which I consider very valuable.

Bluffton, Ohio.

FRANK A. EATON.

OPINIONATED BEE-KEEPERS.

MISS NELLIE LINSWIK HOLDS UP A LOOKING-GLASS FOR US.

LAST May I was called suddenly east; and though I had expected to return soon, the summer passed and November had been ushered in before I walked once more the then quiet aisles of our apiary. One whose summer work for fourteen years has been chiefly among the blessed bees, can not drop all connection with them, and at the same time drop all thought concerning them. Flowers bloomed and faded the long summer through, but ever with a breath of their fragrance came a thought of the bees. The berry-bushes among the lovely rock-strewn hills and valleys of New Hampshire grew white with bloom, but they brought no thought of the luscious fruit to follow as I watched the bees that hovered over them. Later, 'mid the Green Mountains of Vermont I stopped to lay my ear against the rough bark of the basswood, if so be I might hear murmurous music from the nodding blossoms high above me; and, later still, in New York, the lovely plumes of the goldenrod sent my thoughts flying back to my own distant apiary, with a wonder if there the bees might not be gathering amber-hued honey.

But it was in New Hampshire I met my first brother bee-keeper. He walked in one evening with business written upon every line of his face, and fixed his keen eyes upon me. "Your cousin here says you're a bee-keeper, and what you don't know about bees ain't worth knowing. So I'd just like to have you step over to my place, and look at my bees, and tell me why they don't work."

I took the compliment with a grain of salt, doubting much if my cousin could distinguish between a honey-bee and a hornet, but gladly promised to go over and see the bees. Better far for my reputation had I never gone near them!

The next morning I opened the neighbor's gate, and went up the little rose-bordered path to the house; then turning, with a bee-keeper's instinct, I passed around to the rear, and found myself standing under wide-spreading maple-trees in whose cool shade stood the bee-hives. They were the first I had seen since leaving home; and with unspeakable delight I sat down on the soft grass by the side of a hive to watch the busy workers. The morning air was heavy with the fragrance of white clover, and the more exquisite fragrance of the wild grape that trailed its long branches over the stone walls in every direction. In and out in a ceaseless stream went the small toilers of the hive, now brushing my hair as they passed, now dropping, tired and heavy laden, for a moment's rest on dress or hands. A voice at my side broke the quiet.

"So you've found them? And now I'll be obliged if you'll tell me why they don't work."

"Work! But, indeed, they *are* working," said I, with decision.

A sarcastic smile curled his lips. "Yes," he returned, glancing from hive to hive, "I'll admit that they're going in and out pretty lively; but what I want to know is, why don't I get box honey? It's time; for there's Meador, who lives down at the Corners, has taken off I don't know how many pounds."

"How long have your boxes been on?" I asked.

"Haven't been on at all," he replied; and then, seeing my look of surprise, he continued, "you're mistaken if you think I know nothing about bees. I've kept them for some years; and, though I've got precious little honey, I've found out, among other things, that there ain't a mite of use in putting on boxes till they begin to lay out. And where do you see a hive here where they're laying out thick and heavy as they ought?"

I checked a laugh before it had passed my lips, and paused to consider. "How many hives did you have in the spring?" I asked.

"Two; and good strong ones they were."

"And now you have six."

"Yes; and that's not counting the one I gave away for the hiving!"—with a retrospective glance at a far-outreaching branch many feet above our heads. And it was then but the middle of June! The trouble and the only remedy were alike apparent; but there was small chance of my being able to make this opinionated man see things as I saw them. He was a "bee-keeper," albeit on a small scale, and he had made what he deemed some remarkable discoveries. And do we not all know that, as a rule, bee-keepers are blessed with a sublime confidence in themselves? I freely admit, that I have myself two or three pet theories of my own; and, though open to conviction, I confess that I should like to see the bee-keeper who can convince me that I am in error concerning them!

To my disappointment and vexation, the hives proved to be box hives, with all their secrets close locked within them. One hive in particular moved me with mingled pity and indignation. It was one of the old stands, and the bees were going languidly in and out, with none of the stir and enthusiasm of the other hives. Perhaps the young queen had been lost, and the doomed colony, conscious of its hopeless condition, was drifting slowly to annihilation. Think not that I made no effort in their behalf. The short lecture I delivered then and there on the necessity of movable frames, and the consequent advantage in having colonies in a condition for examination and intelligent treatment, if not a very brilliant effort, was certainly an earnest one. But my auditor listened with knit brow and an expression of disapproval. He did not want to go into the business, and he didn't want to be bothered with any new-fangled contrivances. All he asked for was just honey enough for his own use, and no one seemed able to tell him how to get it without more fuss than it was worth. I ventured to suggest that he sell his bees, and buy his honey of Meador; but I don't think the suggestion pleased him. He willingly let me put boxes, six-pound glass boxes, over two of the strongest colonies; and when I discovered in the little workshop a pan of light dry comb, taken from a late swarm brimstoned in the fall, and asked permission to put in some starters,

he watched with evident interest while I pried off the top pieces, and, with the aid of the hot kitchen stove, fastened two starters to each piece, and then pressed it carefully back into its former position. But this was all that I could do; and with the bright anticipations of the morning vanished, I went my way.

Should you ever meet him, this brother bee-keeper of the East, and should you chance to question him, I fear—in fact I am almost sure—he would tell you that what little I know about bees is, in his opinion, hardly worth the telling.

NELLIE LINSWICK.

Very good, friend Nellie. We are glad to hear about our opinionated brother down East. But quite a lot of us are just hungry to know about how that home apiary "panned out" during 1886; and what has become of your sister Cyula? Did she manage that great apiary all alone while you were down East visiting, and the men-folks were busy with the farm work?—In regard to being set in our own ways, I believe you have given us quite a lesson. I can think of quite a number just now who, I am sure, are wrong, but they are so obstinate it does not seem to be of any use to remonstrate any further; and while I am about it, I have been wondering if there are not some things in myself a good deal that way; that is, are we not all of us in danger of becoming too conceited to be taught?

THE BINGHAM HIVE.

SHALLOW BROOD-CHAMBERS VS. SHALLOW HIVES.

I NOTE your talk about "shallow hives," on pages 44 and 45. I see you have not a correct conception of the difference between Mr. Bingham's hive and my own. As I have visited Mr. Bingham on various occasions, besides enjoying visits from him, meeting him at conventions and eagerly reading his well-written literature (including his book, for Mr. Bingham is the author of a book), and, at his suggestion, used one of his hives seven or eight years, I wish to set you right regarding the difference in our hives. I will also say, that Mr. W. H. Shirley is one of Mr. Bingham's students, and used his hive several years before he bought my Glenwood apiary, thus neighboring with me, and working for me winters, and many an hour have we discussed the Bingham hive and system. Allow me to present it, and compare with my own, nearly all of which I believe will be sanctioned by Mr. Bingham, and be in perfect harmony with all he has written upon the subject.

To friend Bingham belongs the credit of demonstrating to hundreds of bee-keepers, that a brood-chamber of a bee-hive has very many advantages when made as shallow as five inches, comb depth, and that such a depth is par excellence for early breeding, wintering, or any other purpose that demands the conservation of heat. I wintered a colony of bees in one of his hives for seven or eight winters, always outdoors, with about half as much packing as my other colonies had, and with perfect success, except once. During that most dreadful winter of two years ago they came through, the strongest in my yard. Mr. Bingham's special claims in this direction are true to my experience.

You speak of it as a "shallow *hive*." The word *hive*, I think, is out of place here; let us say, "Brood-chamber of a hive," and understand each other. All "hives," nowadays, are as deep as you wish to tier them. Now for the difference.

Many times has Mr. Bingham uttered to me and others his detestation of a bottom-bar to a frame. Without such, I consider tiering them impractical. Even if a break-joint honey-board is used between each tier, combs will be fastened to it. I saw Mr. B. cutting them loose when he had his brood-chambers tiered above each other for purposes of extracting. We talked it over at the time. Mr. B.'s brood-chamber is composed of a single tier of frames, extended in length, to give sufficient chamber room at all times.

One of the new and novel functions of my hive is, that its brood-chamber is in two horizontal sections, only one of which is used during contraction, both of which are considered and sold with every complete hive. Mr. Bingham's hive can be inverted, and so can your Simplicity, as you have told us. I claim that neither are made for the purpose, nor are they practically reversible, nor is any other hive without a bottom-bar to its frames. No person interested in reversible hives or frames need fear competition from frames without bottom-bars.

I agree with Mr. Bingham when he says that his shallow brood-chamber needs no inverting. The shallower our combs are, the less liability of honey being stored in their tops; and whatever honey may be found stored in the ends of Mr. Bingham's long frames will not be taken out by the bees by inverting. If combs of the same capacity of his, but in shape of 10 x 10 instead of 5 x 20, were one-third full of honey and two-thirds full of brood, that honey would be removed by inverting that frame, at the proper time.

You speak of handling *hives* instead of *frames*, and the *shake-out function*. Nearly all hives have some little of these functions, even when never dreamed of by the maker. You know that Mr. Hutchinson and myself have often dwelt upon the subject of "readily movable hives," or handling hives, rather than frames, when referring to my modified Langstroth, and to a great extent we so use it. You also know, that when transferring from box hives we often pick them up and shake out what bees we can, especially when we see them clustered near the bottom. Mr. B.'s hives are not supplied with handles for shaking, and his manner of constructing it makes it very heavy; and although I presume, right here, I shall differ with friend B. when I say that I never would depend upon his loop-wire clamp for holding the hive together when being shaken.

It is by virtue of one inversion making the combs completely fill the frames, and that the frames completely fill the case, that the greatest perfection of the shake-out function is secured. The reason Mr. B.'s end-bars do not get "out of whack," even though no bottom-bar is used, is not only because they are short, but the top-bar is $\frac{3}{4}$ square; and, I think, in most of Mr. B.'s hives he nails this bar corners up and corners down; thus: $\diamond$ This gives him a cheap V guide, and a good one too, but no bee-space above.

I am astonished that you should mention his alternating the sections of hives. His *brood-chamber* is not in sections, and the possible alternating of several brood-chambers is just as true of any of

your Simplicities. It is true, that Mr. Bingham practiced laying his hive upon its back for making certain examinations and clipping cells, and he illustrated the performance to me in his apiary, but he didn't first shake out the bees, nor is his construction especially adapted for working from both sides, as I have made mine.

I feel indebted to Mr. Bingham for what he has done by way of clearing our minds of false impressions against extremely shallow combs. The claims of my invention are on page 14 of my circular, and I think both you and Mr. B. will see that none of them are anticipated in his hive. If you think I am mistaken with regard to his hive satisfactorily carrying out the functions of mine, I would suggest using some of each, side by side. In doing so, please use both styles just as we make them. Do not inadvertently wrong us by any alterations.

I have devised some ten or twelve different ways of constructing my hive without the outer case; like Mr. B., making the ends of the frames take the place of the ends of the case; and I have abandoned them all for what I believe to be very good reasons. You can have the reasons and the models any time you wish to print them.

In the *A. B. J.* Prof. Cook said: "If any one honestly believes it, let him say it is a worthless hive and system. But, alack the day when any considerable number of bee-keepers say it is not Mr. Heddon's."

JAS. HEDDON.

Dowagiac, Mich., Jan., 1887.

VOLATILE OIL IN HONEY.

THAT WHICH GIVES FLAVOR TO HONEY.

IN all discussions in regard to ripening honey, one essential fact has been entirely ignored, and yet the quality, if not entirely, is more dependent on it than on any other. That honey must be of a certain consistency, is conceded by all; so quality first and quantity next is what we are all in pursuit of; and how to get the latter without failure of the first, is yet an open question. Admitting proper consistency, quality, then, is due to its peculiar flavor, which is derived from the nectar of the flower.

All flowers and plants possess a peculiar and distinct odor, which is due to a volatile, or essential oil, peculiar to itself, and this same oil we find in the nectar of the flowers; this it is that gives honey its distinct flavor. When flowers are macerated in water, then distilled, the essential oil of the flower passes off with the steam, and, if condensed, the oil is found in minute quantities floating on the water; and this, as its name indicates, is very volatile; and, if exposed to the atmosphere, in time all evaporates. Thus the flavor of the honey is dependent on the quantity of this oil present in it. Some flowers possess more of it than others; and, as a natural result, we find some honey with more of a distinct flavor. If the retention of this oil is desirable, then that method by which there is the least loss is the one we are in search of. That we have not yet attained this, is evidently a fact; but that it is attainable is beyond question, and I doubt not but that careful experimenting will yet give us a standard to go by.

G. W. BRODBECK.

Indianapolis, Ind., Jan. 20, 1887.

Friend B., while some of this volatile oil

is a good thing, I believe I should, as a rule, prefer that the bees evaporate out the greater part of it. Honey newly gathered from basswood has altogether too much volatile oil to please most people, and the same may be said of the horsemint of Texas, and many other kinds of honey. If letting the honey get thoroughly ripened deprives it of this volatile oil, I should say let the oil go.

HUMBUGS AND SWINDLES

PERTAINING TO BEE CULTURE.

We respectfully solicit the aid of our friends in conducting this department, and would consider it a favor to have them send us all circulars that have a deceptive appearance. The greatest care will be at all times maintained to prevent injustice being done any one.

DELOS STAPLES AND THE BLUEBERRY-BUSINESS, AGAIN.

ED. GLEANINGS:—I notice that the blueberry man has commenced advertising under a new name and address; but when the circulars come to hand they come under the name of L. D. Staples. See inclosed circular, just received. On account of new subscribers, would it not be best to caution readers of GLEANINGS? I lost some four or five dollars by investing in blueberry plants with Staples. I could get no satisfactory answer from him. I inclose an advertisement cut from one of the Jan. monthly agricultural papers, and have seen it in at least one other.

Exter, Pa., Jan. 31, 1887.

P. SUTTON.

I too, friend S., have noticed the blueberry advertisement, and I judged it was probably Mr. Staples under another address. Below is the advertisement mentioned in the letter:

BBLUEBERRY. A valuable fruit to grow for pleasure or profit. Price list free to all. An agent wanted in every town. Complete outfit furnished free. Address, Willow Ridge Fruit-Farm, Portland, Mich.

I will explain to those who have been victimized by Mr. D. L. Staples, that he does not send out any *plants* at all. He sends only some dry sticks, with a pretense of putting a little moss around them. They never grow, and he never makes any thing right. Will our friends of the agricultural press please pass him around? The circular, sent in response to an answer to the advertisement above, brings the old blueberry circular, signed L. D. Staples, Portland, Mich. He was so thoroughly advertised under his old name and address that he thinks to get new victims by the "Willow Ridge Fruit-Farm" dodge. By the way, we are very much obliged to the friends for promptly forwarding any thing that seems to have the semblance of a swindle. Let us help all honest men to live; but at the same time let us help all swindles to die, and that quickly.

Since the above was in type I notice several of the agricultural papers have also taken the matter up. Now, is it not time, dear friends, that a complaint be sent to the Postmaster-General, and that a protest be made against delivering mail matter to Mr. Staples? He has *swindled* enough people already.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from Jan. 15.

CHAPTER XXXV.

For ye are bought with a price.—I. COR. 6:20.

It is a happy thought to me, dear friends, that I am bought with a price—that I belong to Christ Jesus. The reason why it is a happy thought is because I have a right to feel that he has his plans, even for a poor humble life like my own; that he has something for me to do, and is watching me with loving care. I have felt that he called me to write this book; that it is his wish that I should write it, and that he has a message that I may, through the book, carry to you, my dear readers. "What to do, and how to be happy," is a great theme; and when I undertake to tell the people of the world—that is, such a part of the world as may be interested in listening to what I have to tell, it seems to be almost a sacred commission intrusted to me. This book is almost constantly in my mind. When I go away from home I at once begin to think, "Now, what shall I find during this trip that will be of value to my fellow-men, and that will properly come within the province of this book?"

About the middle of January I was called to a convention of bee-keepers in Albany, N. Y.; and when I started out it was with a prayer that God would help me in my feeble efforts to grapple with this great problem of something for the masses to do. In consequence of snowstorms we did not reach Albany by daylight, as we should have done had it not been for delays. For my part I was rather glad we didn't, for I could look out of the car window and catch items in regard to something to do. The first thing that met my gaze was crowds of people and numbers of horses at work on the frozen surface of the Hudson River, gathering the ice-crop. Sure enough, here is something to do in the winter time; and, like agriculture, the work seems to be a worthy undertaking. I have noticed for quite a little time past, that ice is used in many of our large hotels and eating-rooms, almost as much in winter as in summer. At the Globe Hotel, where I stopped for breakfast, the first thing the waiter did was to bring a handful of pieces of ice, not quite as large as a hickory-nut. These were put into a clean goblet, which was then filled up with water. Every guest was furnished with ice-water, whether he cared for it or not. The water was pure and soft, and I enjoyed

a good drink of it, even in winter. If you take a drink before the ice has had time to cool the water too much, it is not unpleasantly cold.

After breakfast, as there was some little time before the convention opened, I made inquiries for greenhouses devoted to raising winter vegetables. The clerk at the hotel said he did not think there was a greenhouse near the city of Albany, for such things. He said they got their lettuce, radishes, etc., from the city of New York. I knew by experience, however, that it is not well to give up in such a search, so I inquired for the market. Before I got to it I caught a glimpse of great crowds of men at work on the river again. Here was a broad field for employment, even in the winter time, so I decided to investigate. On the bank of the river were not only great numbers of sleds drawn by horses, but there were ice-cars drawn by locomotives, taking the ice away. The huge blocks were carried up the bank by an apron made of endless chains; and as they struck the platform, men and boys who were expert at the business quickly grasped the blocks with poles having steel points on the end, like the cuts below.

ICE-HOOKS, USED ON THE HUDSON RIVER.

It is wonderful to see the dexterity with which they would make these huge blocks fairly spin where they were wanted. They seemed to almost run of their own accord on to the sleds until the sleds contained all the team could well draw. The minute the sled was loaded, a trained teamster took it out of the way, and another one quickly slid into its place. One new at the business, like myself, would say that every movement *happened* to be a lucky one; but there was not any "happen" about it. They had learned the trade, and knew how. Then I clambered down the ladder on to the frozen river. The

blocks of ice were swimming of their own accord again (at least it looked so to me), along the narrow channel, or canal, of clear water. Of course, they had a little push once in a while, from men stationed at intervals, armed with these same ice-hooks; but some way it happened that every time the chain apron came around it caught a block of ice just right, and up went the ice on the inclined plane. I followed out into the river to see what made those blocks sail along just so far apart, and in such regular order. Pretty soon I came to a man standing on a heavy plank laid across the channel. In his hand was a tool something like the one figured below.

SPLITTING-BAR, SUCH AS IS USED ON THE HUDSON RIVER.

Well, the blocks as they came up to him were in pairs—that is, there were two together, with a deep groove where they were to be separated. As they sailed under his plank he quietly let his chisel down into the

that looked very much like cultivators. I asked one of them if it was as much fun as cultivating corn. He looked at me a moment, and then smiled; and his smile convinced me that he was one of *my neighbors*, even if he was away off here in Albany, while I lived in Ohio. I told him they might be thankful for one advantage they had over working in a cornfield. He asked me what it was, and I suggested that they did not have any mosquitoes or flies to bother the horses. It was a bitter cold morning, but the workmen seemed to enjoy their work notwithstanding. They did not have any boys to ride the horses. The horses were all led by men. Very likely the boys were at school, all of them, and may be a boy would not use care enough in leading a horse so as to mark out the work accurately. The cultivator used was something like the figure below.

AN ICE-MARKER, TO BE DRAWN BY A HORSE.

groove, and the double block was separated. A little further up stood another man with a similar tool. Now, the ice, as it came to *this* man, was in a long strip composed of perhaps 40 blocks, say 2 feet wide and 20 feet long, something like the diagram figured below.

A STRIP OF ICE BEFORE IT IS CUT UP.

Well, as this block of ice ran under the plank, whereon stood this second man, he chiseled off two blocks, where you see the light dotted lines in the diagram above. The next point to be considered was, Where do these long strips come from? By this time I was out in the middle of the river, and men and horses were drawing things

You will notice that one side of the plow, or cultivator, is a long plate of steel, having a sort of blade on each end. Well, between the handles of the plow is a rod with a loop on the end. The steel blade slides into one crease, and guides the plow while it cuts another; and when you get to the end of the row, by means of the rod with a loop on the end you throw the steel blade, or guide, to the other side, so you can go back again. This measures the blocks of ice absolutely. After this marker has passed, another horse takes the regular plow shown below.

AN ICE-PLOW.

This plow will cut in about five or six inches; and even if the ice is a foot thick, or more, the ice-chisels already described cut it without trouble. After the horses have finished their work, the ends of these long strips are cut loose with an ice-saw. Then a man with an ice-chisel like the one below goes along the groove where he wishes the large cake to separate, and strikes repeated blows, say at intervals of ten feet.

ICE-CHISEL.

After he has struck one or more times, he can tell by the sound that the ice has split. A click is heard when the crack starts. If you have ever heard a pitcher break because the water inside was freezing, you will know what it sounds like. Finally, before you know it, the great cake moves off into the water, and he has no further concern with it. The men with the poles start it on its march. In loading the ice on to wagons, tongs are sometimes used, like those figured below; but the regular ice-men hardly ever take the trouble to bother with tongs.

ICE-TONGS.

Occasionally saws are used for a special purpose, like the one following.

AN ICE-SAW.

Every thing seemed to be going on so pleasantly I was wondering if the ice-business was not an exception to many of the great industries that spring up and cause trouble by strikes and differences between labor and capital. Pretty soon, however, I had reason to feel that Satan makes his way out on the frozen river, as well as into factories, mills, and warehouses. One of the men was so much intoxicated that it seemed every moment as if he would go into the water, and I was told that a great many go under the ice and are drowned. If whisky gets among such a crowd, is it any wonder? and is it any wonder that strikes and riots should come in too? So many ice-houses have been burned by mobs and rival inter-

ests, I was told that it is a hard matter to get them insured. Between Albany and New York the river is literally alive with ice-companies, and great edifices, or monstrous buildings, loom up to hold the ice-crop. A young friend whom I met later has furnished me some important facts in regard to the matter, and I will here let him supplement, in his own words, what I have already told you.

HARVESTING ICE ON THE HUDSON.

One of the greatest industries that has grown up in the Hudson Valley in the last ten years is that of harvesting the crop raised chiefly by the aid of Jack Frost: viz., the ice-crop. Immense houses, all above ground, are built all along the river, and quite close to it. These buildings are usually about 40 ft. in height, with a mansard of 10 ft. additional, which is used as a loft for storing salt-marsh hay, used for covering ice at top. Each house contains from four to sixteen rooms, each 50 x 100 ft. on the ground. These rooms contain about 5000 tons each. The outside walls and partitions are from 14 to 22 inches thick, and are filled from floor to top with sawdust. The bottom is laid with plank or boards to keep the ice from contact with the earth. The rooms have the width facing the river, and stand in two tiers, front and back. Each two rooms, front and back, are connected by a narrow opening, and are filled by one elevator. These elevators are on inclined planes running from the top of the building to the edge of the dock. Aprons are then let down beneath the surface of the water, and a pair of endless chains, having cross-bars every six feet, catch the cakes and carry them up the elevator, one, two, and three cakes to a bar. A little way up the elevator is a simple contrivance for reducing the ice to a uniform thickness. (The above is a new invention, and has not come into general use.) The cakes are carried up to certain openings to which runways are affixed, leading into the rooms. After the ice passes through the opening in the elevator it is carried into the building by gravitation. As the building fills, all lower openings are closed, and the one next higher is opened. The machinery is operated by a powerful steam-engine.

The cakes, which are 22 x 32 inches, are placed one tier, or course, running lengthwise, the other crosswise of the room, breaking joints. No cake is allowed to touch its fellow except at top and bottom, a space of 3 inches being left all round. This facilitates taking the ice out. The loss in space is more than compensated by the superior condition in which the ice comes out, very little being broken by this method of storing.

When the ice is of sufficient strength to hold a team, should there be a considerable fall of snow a force of teams is put at work scraping the ice clear of snow. (For a 40,000-ton house a large number of acres will be cleared.) This clearing is done for two reasons. 1. The ice will make faster; 2. Clear water ice is preferable to part snow ice, on account of its superior keeping quality.

When the ice is of proper thickness, say 10 to 12 inches, a field of a number of acres having been cleared, two straight lines are laid through the center, and at right angles to each other. A marking ice-plow, which cuts to the depth of two to three inch-

es, is then run in these lines. The marking-plow has an outrigger attachment which makes a scratch, or mark, parallel to the first furrow in which the marking-plow runs on returning. When the field is marked, plows cutting to 6 inches in depth are run through the furrows across and back. These are followed by plows cutting yet deeper. Two-thirds of the thickness of the ice is usually cut with plows, rendering the cutting with chisel-bars an easy matter. The plows are worked by horse power. Large blocks (12 x 20-foot cakes in size) are then sawed clear through by hand, and floated into a canal about a foot wider than the block of cakes. Care is taken to stop up with snow the end of furrows made by plows, to prevent water running in and freezing. In this wide canal the blocks are broken into strips by three or four men, with implements similar to a gardener's spading-fork. These strips, containing 12 cakes, are kept moving by men (armed with pike-poles) who stand on either side of the canal. Smaller canals, a little wider than the cakes are long, open into the larger canal, and at right angles to it. There are as many of these smaller canals as there are elevators in the building. Here the strips are broken into single cakes by a chisel-pointed bar. It will be remembered, that the breaking into strips and cakes is rendered comparatively easy since the plows leave but from four to six inches uncut. The cakes are pushed into the aprons where the bars of the elevator, above described, catch them and take them up the incline.

A house of 4000 tons' capacity requires 200 men in the building and field, and can be filled in 12 days.

HINTS TO THOSE WHO PUT UP THEIR OWN ICE.

The great difficulty experienced by many who put up their own ice, or, in fact, any who have it put up in a small quantity, is to have it keep well. A few hints, gathered from one of the most successful practical ice-men on the Hudson River, may be of value to some.

Houses built all above ground are least expensive. A wall laid in mortar, reaching below frost, and coming just far enough above ground to clear the sill from the surface, should be built. Sills may be made of two two-inch plank, spiked together, or of other material. Sills should be wide enough to take 2 x 12 studding. Wide studding are used in order to give ample space for sawdust filling.

A house 12 ft. square inside, and 10 ft. high, will hold 32 tons; same height, 15 x 15, holds 50 tons (45 cubic ft. to the ton). Siding nailed to studding inside would be best of hemlock; outside, to suit

taste of builder. Boards or plank should be laid on the bottom to keep ice from contact with earth. Care should be taken to get sawdust filling well into the corners. A door 12 ft. high, by 3 or 3½ wide, in two sections, upper and lower, is cut in one end. A cleat is nailed to the studding, just inside the door, and another to the further side of the studding, to hold short boards, which are put in as the house is gradually filled. As the courses rise, a block and tackle are used in hoisting. Swale hay or rye or oat straw makes a good and clean covering for the top. Get enough on, and settle it well.

Where a number of families in a farming neighborhood put up ice it would be economy to have an ice-plow. A first-class one, with swing-marker attachment, can be obtained for about \$50.00. By a number clubbing together, the cost would be inconsiderable. Getting in ice, like thrashing, requires quite a force of men to work it to advantage; and if neighbors go at it together in the same way, the labor will be materially lessened. With a plow and a couple of chisel-bars, very little sawing need be done, and yet have cakes in good shape for stowing. About 22 x 32 inches is a very convenient shape for handling.

A nine-inch plow will make a furrow of the same depth in ice. One stroke of the chisel-bar will detach it, and leave a good even face.

GEO. M. WATKINS.

Cedar Hill, Albany Co., N. Y., Feb. 7, 1887.

As more people are out of work during the winter than at any other time during the year, I think it will be an excellent idea to lay our plans so as to put in the time during these winter months, and the ice-business can be profitably carried on in almost every locality. The market-gardener will many times find it quite convenient to have some means of preserving perishable products (strawberries and the like), and the use of an ice-house may save him a good many dollars, even if he does not think of going to the expense of cold-storage buildings. The young friend who furnished me the letter in regard to the ice-business above, was also interested in market-gardening; and when I told him about my searches for greenhouses for growing vegetables, he said he thought he could help me, and I will tell you something about it in our next chapter.

CHAPTER XXXVI.

He that tilleth his land shall be satisfied with bread: but he that followeth vain persons is void of understanding.—PROV. 12: 11.

We were on the streets at the time; and when I mentioned it he turned abruptly and entered a green-grocer's, situated a little below the sidewalk. Just at that moment it struck me that one who proposes to deal in lettuce, celery, beets, turnips, and articles that are apt to dry up if precautions are not

taken, is very much better located in a basement than in a store level with the walk. Mr. W. mentioned the purpose of our visit, and the proprietor was very courteous and obliging. So much for having somebody who is acquainted in a large city, to assist you. The storekeeper showed us different

kinds of celery, and even gave us some sample stalks to taste and admire the flavor. No lettuce was in sight; but when we mentioned it he opened some round boxes not unlike wooden cheese-boxes, but smaller. Each box contained perhaps a peck of lettuce. This quantity is not large enough to cause it to heat, and yet when kept shut up in a box in the somewhat damp and cool air of the basement it kept in excellent order. He mentioned several greenhouses in the vicinity of Albany where lettuce was grown; but they both agreed that my best place would be to go out to "Frost's." Afterward we found lettuce for sale in the basement of the very building of the Globe Hotel; and yet the clerk at the hotel didn't think any lettuce was raised in or around Albany.

As our bee-convention was to meet at nine o'clock, I was up and had my breakfast long before daylight. I was on the stand waiting for the street-cars at the time they were to start; but after having waited for 15 minutes in the cold, and no street-car made its appearance, I concluded to be independent and go on foot, even if it was about four miles. At least one of the four miles was up hill, for Albany is "a city set on a hill," or, rather, a sidehill. How I did enjoy that walk! The hill slopes toward the rising sun; and as his rays poured full upon me, my spirits began to revive, as they always do when I can go on foot, and the sun shines. I fell in love with the small boys, and even with the dogs and horses as I passed. I even loved the saloon-keepers who stood at the doors of their places of business, pretty thickly sprinkled along the way; but I did not fall in love with the business they followed. Finally the broad grand country landscape opened before me, and here too I found throngs of people busy filling their ice-houses. The ice was taken from little streams that had been dammed up purposefully, as it seemed, to form ice-ponds. They may have been carp-ponds also, for aught I know. Just beyond where these people were at work I saw Frost's establishment, surrounded with evergreens for windbreaks. His greenhouses were mostly located on a sidehill. There were five of them in number. Mr. Frost is a practical man. There is nothing of the style of grandeur of Peter Henderson's floral establishment to be seen in Mr. Frost's gardening operations. I found him at work with his boys, among the greenhouses. The one I first entered was full of early Silesia lettuce; and for once in my life I was satisfied with the view of a real live

lettuce-house. These houses are just about as cheap as they can be gotten up; in fact, some of them had walls made by driving stakes in the ground, and filling in with coarse manure. On top of these were ordinary greenhouse frames, with just enough slant to carry off the water. They were warmed by stoves set in a hole dug in the ground. In many places the glass is so low that one is obliged to stoop to walk through the house. This gives the advantage of getting the glass close to the plants—a matter that I have emphasized strongly, as you will remember, in Chapter X. The walks are a little below the surface of the beds. In many of the houses the beds are simply banked up as we would bank up beds in a flower-garden. The house that pleased me most, however, was an asparagus-house. I have tried to give you a picture of it on the next page.

The size of this house is 125 feet long by 40 feet in width. The walls are made of very cheap material, and rise to the height of only three or four feet. It is built along a hill-side sloping to the south and east. Along the center of the ridge is a piece of shingle roof, perhaps four feet wide. This runs the whole length of the building. There are three rows of 3x6-foot sash each side of this center-piece of roofing. Now, a short man like myself can just walk under the center-piece. If he goes out under a sash he will have to stoop a little, and the row of sash next to the eaves has a pretty sharp slope so as to make the low walls around the outside answer. The sash is supported by stakes driven into the ground in rows the whole length of the building where one sash laps on to the next. These stakes are perhaps six feet apart, and they are simply cheap stakes split out like rails. Five common coal-stoves warm the spacious building. Each one is placed in a circular pit, dug in the ground perhaps two feet deep, and the pipes run perhaps fifty feet or more under the glass before they go into the open air. This takes pretty much all of the heat, without smoke, before it goes into the open air, and is economy in fuel. Now, this sash is to be entirely removed as soon as warm weather comes, to let the asparagus grow in the natural way in the open air. In fact, during the greater part of the year this asparagus-house is nothing but an asparagus-bed with low walls around it, and the strip of roof through the center. The asparagus, however, is planted much closer than in ordinary culture. Mr. Frost told me the rows

were only a foot apart, and the roots only six inches apart in the row. Of course, it is manured up to the very highest notch. The soil on these hillsides is a sandy loam, and the immense quantities of manure put on it have made it black and strong, like the Arlington soil. In order to get the roots ready for this forcing process, the whole bed is covered in the fall with the best strong manure. The fall rains and snows are permitted to cover it. In order to let the ground freeze, the manure is raked off after it has been pretty well soaked by the rains; then during the latter part of December, when every thing is frozen up solid, the glass is put in place, and the stoves started. Under the influence of the heat of the stoves

you suppose asparagus brings a bunch here in Albany during the middle of January? Only *one dollar*, dear reader. I wonder if you can guess who pays a dollar a bunch for asparagus in the winter time. Why, no less a personage than the President of the United States. Mr. Frost had been in the habit of supplying the President for a good many years; and just a few days before my visit, the President sent word that he could not find a bit of asparagus in Washington or Philadelphia, and so he had to go back to this old friend. Mr. Frost gets a dollar a bunch at wholesale for his first cuttings; and by the time it reaches the consumer it costs \$1.50. I asked him if they hadn't got to shipping asparagus from the Southern

GREENHOUSE FOR RAISING ASPARAGUS IN THE WINTER TIME.

and the rays of the sun through this low sash, the ground thaws up, and the asparagus-shoots begin to peep out by the middle of January. Great beautiful shoots were now peeping forth in a circle eight or ten feet away from each one of the stoves. The nearer the stoves were, the larger the shoots. To help pay the interest on the cost of such a quantity of glass, a crop of radishes is put between the asparagus rows. These radishes come off before the asparagus comes into heavy bearing.

Do you wonder, friends, that I inwardly thanked God for the beautiful sight spread out before me? I felt amply repaid for my four miles' walk—yes, and for my whole trip away off here to York State. What do

States, as they do strawberries, cucumbers, etc. I am inclined to think that, like celery, the cold weather of the North is needed to bring this plant to perfection; for Mr. Frost said he had repeatedly sold asparagus in the winter time, to be shipped to New Orleans.

The sun was now shining brightly through the sash. I walked up and down that glass-covered hillside, admiring the dark rich loam that formed a path under my feet—admiring the great broad healthy-looking leaves of the radish-plants as they pushed forth from the dark rich soil, and admiring the asparagus peeping forth in obedience, as it seemed, to God's command. Yes, truly has God given us dominion over the fish of the sea and the fowl of the air, and, too, every herb bear-

ing seed; and I felt, too, that it was in obedience to God's call that I was away off here on this beautiful January morning. I asked if the same plant would yield a crop year after year. He said he had found no trouble, providing he stopped cutting in time to allow them to make a good growth, and bear seed, and then keep the glass off long enough to allow the whole bed to freeze up so as to make a real winter of it before bringing in the artificial spring. Time was passing, however; and, much as I enjoyed this beautiful spot, I should soon be wanted at the bee-convention, and I began to feel that my good friend by my side feared I was a little *too much* interested. My many and eager questions might have made him feel that it was not best to give away the secrets of his trade too much, for he was evidently an old-countryman.

There was one point about Mr. Frost's work to which I wish to call special attention. He did not build these five great vegetable-greenhouses all at once. He increased his area of glass as the market demanded it, and he did not throw away hundreds of dollars until he could be sure he was going to get it back again. The closest and most careful economy was studied at every point. When I suggested a steam-boiler in place of all those stoves, he declared most emphatically that the interest of the money would eat up all the profits, and I am not sure but he is right about it. The great expense of this gardening in winter is the glass. The sash were cheap and light, and the panes of glass were small — about 6x8, if I am correct, so that a breakage could be made good at small expense; but even with his rude and cheap appliances, the quality of his vegetables was equal to any thing I have ever seen anywhere.

It may be well right here to put in a word about extravagant expenditures in business; and in advising you how to be busy I should make a sad, sad mistake if that advice should result in inducing you to get still deeper in debt, and end up by having nothing to do after all. Be very careful about making purchases, and purchase a little at a time. I often tell young bee-keepers to commence with one or two hives of bees. When these two hives of bees have afforded profit in your hands, then, but not before, increase the number. The same in regard to sash for raising early vegetables. Try a few sash. If they are a paying investment in your hands, and under your management, then try a few more, but do not enlarge too

fast. Florists tell us that if a plant is feeble, and seems likely to die, let it alone. Give it sun and air, but don't give it liquid manure, nor even water, until it starts to grow. Then give it a little water; and if that seems to prove beneficial, give a little more. When it comes to be rank and strong, and if covered with a great amount of foliage, it can take water in abundance, and not be harmed—yes, even strong manure, and it is ready to take it up and make great strong branches and leaves. So must the young gardener start. Giving him money or credit would be like the strong manure or guano water to the feeble plant—it would kill it outright. Get a healthy growth started first. I would not even buy seeds or tools without carefully considering the matter.

Only last summer a bright intelligent young man came to me for vegetable-plants. He paid cash down at first, and seemed to be enjoying his work, and doing well. Finally an opportunity offered for him to do quite a business, but he had not the money to pay for his plants. Contrary to my better judgment I gave him a few weeks' time on them. Then came severe droughts and other discouragements, and he was obliged to give up the business without being able to realize enough to pay his honest debts. I meant to do him a kindness when I trusted him, but I fear it was an unkindness. Don't go in debt, boys. Use wisely what money you have got, and use it judiciously; but don't use money you have *not* got.

At our teachers' meeting the other evening the matter of buying lemonade, soda-water, and the like, came up. One of the teachers surprised me by a remark something like this:

"My friends, I would almost as soon see my boy buying beer and cigars as to see him buying soda-water, lemonade, and pop, for it is only a question of time. Standing around a bar, getting drinks, and treating each other, is going through the motions that lead to intemperance and crime."

I was a little surprised, and turned to an old gray-headed deacon who has been many years of his life superintendent of the Sunday-school, and I waited to hear him tell our young friend that he must not draw the lines too close; but, to my surprise, he smilingly said he felt just about as the brother had expressed it. I have been thinking of it since, and it startles me somewhat. Is it wrong to buy lemonade? Well, my friend, I feel pretty sure of this: If a young man were coming to me for advice, and he were

starting in the business of gardening, I should feel a little discouraged to see him buying lemonade at a restaurant. He can not afford it. Ernest just now informs me that President Fairchild, of Oberlin College, once told the students that they could not afford to buy lemonade by the drink. Lemonade is beneficial to the health, without doubt, and the use of lemons in the family is to be recommended; but you can buy them by the dozen, so the expense is not more than two or three cents each for nice ones, and a good lemon will make a fair pitcher of lemonade for a small family. When we have strawberries, currants, pie-plant, and such like tart fruits and vegetables, they take the place, to a great extent, of the lemonade. The most dangerous part of this practice, however, of buying drinks—even temperance drinks—is the fashion of treating. I have known farmers' boys to be induced to use their hard earnings to treat a lot of girls to ice-cream or lemonade, when the boys could poorly afford it. Your comrades may call you stingy; but it is far better to be called stingy than to have it said you are not able to pay your honest debts, or to clothe yourself decently, and get a tolerable education.

Last summer I found that one of the boys who went with our fruit-wagon was buying lemonade almost every day, and his wages was only $7\frac{1}{2}$ cents an hour; and I knew that, after paying for his board and clothing, he could not *afford* to buy lemonade; and when I heard that he was not only buying it for himself, but was treating others, I decided I could not keep him. These are little things, dear friends; but it is little things that turn the scale between success and failure in life.

In speaking of the ice-crop on the Hudson River, I alluded to the fact that ice is getting to be a thing of every-day use. Well, I believe it is a fact that good drinking-water, cool and refreshing, is one of the great agents in discouraging intemperance. I was once in the habit of drinking beer to some extent. It was recommended by our family physician, and I thought I needed it. A great many times, when I felt as though I must have it, I found that, by taking a drink of ice-water, I did not care particularly for the beer, after all; and no doubt

thousands will find it easier to break away from these habits where nice cool drinking-water is always at hand. The Women's Christian Temperance Union is doing a great work in providing convenient and attractive drinking-fountains. Putting up and filling ice-houses may greatly help this work around our homes; and what other one thing is it that makes a place more homelike than sparkling water and a bright tin cup, not only to invite the members of the household, but the wayfaring man as well? Dear reader, is the nice tin cup with the water to accompany it one of the adjuncts of your home?

I do not know how my friend Frost stands financially, but he is a hard-working man, and one who makes his money by the sale of fruits and vegetables, and I have never visited any one where there was such economy practiced in every thing as at Mr. Frost's. Every thing that was not in actual use was carefully put away under cover, and yet there was no extravagant outlay of money anywhere. He has a pretty residence, and a nice yard, but nothing to indicate that he wished to make a show or any great display in the world. The evergreens were beautiful, but it was evident that they had been planted as windbreaks to his greenhouses, as well as for ornament.

Twenty-four hours after my visit to the asparagus-house, I was talking the matter over with Peter Henderson. Said he, "Why, Mr. Root, you have just given me information on a point I particularly wanted to know about. It is this matter of giving plants their regular winter rest, or nap. When your name was handed me I was just dictating an article to the stenographer, on this very subject. We florists have found to our sorrow, that if this winter rest is not given to plants that demand it, sooner or later our stock will run out. I should not have thought it possible for Mr. Frost to get a good growth, year after year, in this asparagus-house, but with the brief natural winter he allows them before commencing to force them by an artificial spring, it is probably practicable. We have just decided that something of the same kind must be managed with our violets that we force year after year for early spring bloom."

To be continued Mar. 15, 1887.

WHAT DOES IT COST PER POUND TO PRODUCE HONEY?

E. FRANCE TELLS US WHAT IT COSTS HIM PER POUND.—OTHER INTERESTING FACTS FOR THE TRADE.

IT is not a very easy task to make out just what honey does cost per pound. In the first place, we have got a good deal of money invested in bees and hives—buildings, wagons, machinery, horses, and fixtures of one kind and another that we have to use to run the business. All these things cost money; and it takes no small sum, either, to run 500 colonies of bees. The interest on the money, and the wear and tear of the fixtures, will be about as much as the actual cost of gathering the crop. But let us see about what it did cost us to gather our last crop, aside from the above investments.

Eight boys' wages for 27 days.....	\$108.00
Board for the 8 boys, 27 days.....	80.00
1 man at \$1.50 per day, 27 days.....	40.50
117 barrels, at \$2.00 each, to hold the honey..	234.00
Rent for 5 yards of bees, away from home.....	75.00
1 hired team at \$1.50 per day, 27 days.....	40.50
Oats for 4 horses, 2½ bu. per day for 30 days, at 35 cts. per bushel.....	26.25
Hay for 4 horses, 30 days.....	15.00

Total cash paid out for the crop.....\$619.25

If we add \$18.00 more to the above figures, the cost would be just about one cent and a half per pound, as the amount of the crop was 42,489 lbs. of honey. Now, besides the above expenses, I have figured up, at one-third less than cost, the worth of the investment in materials, such as land (one-half acre at home), buildings, bees, hives, wagons, two horses, extractors, foundation-machine, and a great many other fixtures, too numerous to mention. On this amount I computed the interest at 7 %. I then added one-half the amount of the interest, for the wear and tear of the fixtures. Then put in \$300 for the pay to E. France & Son for caring for the bees, and overseeing the business for one year. To these items I put in \$50.00 for foundation used. The total of all these amounts to over \$800, or very nearly 2 cents per pound for the cost of land, tools, fixtures, etc., in the production of honey for the year 1886. Add to this the 1½ cents (the cash paid out for the production of a single pound of honey), and we have the total cost of the crop at about 3½ cents for a single pound. But, remember, the year 1886 was an unusually good one for honey. After we have secured the honey it is a long way from being cash. It has to be sold. But it is not like a bed of strawberries. We can take our time to sell, any time during the year, and we can keep it over if we don't sell the first year.

BLACK BEES REPELLING MOTH MILLERS.

I will just say, we have no trouble with the moths or worms in our hives. As long as a hive contains a good strong colony of bees there is no danger of moths. Keep the bees strong, and they, whether blacks or Italians, will keep clear of moths. I see but very little difference. All the trouble we have with the moth is to keep empty combs from being destroyed until we can use them. We winter all our bees outdoors, and we are not one of the lucky kind who never lose any bees in winter. We always lose some. If a colony dies before we are done with zero weather, the worms, if there are any, freeze to death, eggs and all. Such combs we can keep in the hive, shut up tight until July. But if a

colony dies, or swarms out in the spring, after the cold weather is over, the combs left without live bees will soon be wormy. It will be the same, whether they were left by black or Italian bees. I don't see any difference. We have both kinds of bees, and, of course, have a better chance to know than we would if we had only one kind. There is a great deal said about the Italian bees being moth-proof. But a large part of such talk is from those who keep only Italians. If they are kept strong they are safe, and so would be the blacks. Now, I don't want any one to think that I am opposed to the Italians. I am not, by any means; but I do think they are overrated. Still, I think the bee-business has gone ahead faster than it would without them, for this reason: *They are handsome.*

If I buy a queen, and pay a few dollars for the one bee, I shall be very likely to give her the best of attention, make as much out of her as possible, raise several queens from her, and those queens have to be supplied with bees. First you know there is a nice apiary built up, when, if the same queen had cost nothing, there would not have been very much interest taken in the matter. As for the blacks being worse to rob than the Italians, I don't see it. But we scarcely ever have any robbing, as we have no occasion to work with the bees when there is no honey coming in.

FRANCE'S HONEY-EXTRACTOR.

In your notes on my article in GLEANINGS for Dec. 15, page 977, you ask a few questions which I will try to answer. First, about my home-made extractor. It is essentially the Chapman extractor with France's improvements to make it suitable for our work. The first extractor I got was a Winder machine, made for me after I sent him one of my frames. The whole can whirled around. There was a hole in the center of the bottom, about as large as my finger, for the honey to run out when the machine was at rest. I got along with it as long as I was alone, or had one hand to help me. It bothered me a good deal about choking up—the outlet was too small. A little piece of comb, or some loose cappings, would choke it up, and then we would have to punch it out. One of my neighbors has a Chapman machine. The can sits in a frame, has a gate under the bottom to draw off the honey, and has a revolving comb-basket inside. I liked that better than my revolving can, so I sent two frames to Mr. Chapman to have him make a machine suitable for my frames. As my frames were large, the machine would have to be of an extra size. I told him to make the comb-basket out of wire cloth, three meshes to the inch. In due time I received the machine. It was a big improvement over my old revolving can, but it did not fill the bill. First, the wire cloth in the comb-basket was five meshes to the inch instead of three, as I ordered. The trouble was, our frames stand on the bottom, and have three heavy nails driven into them to keep them apart. Those nails would go through the cloth, and bothered me to get the comb out of the basket. A three-mesh wire would let the nails out easily, and scarcely ever make any trouble. The honey-gate was too small—it would choke up as badly as our other machine. I took the gate out and put in a larger one. I use a two-inch gate. When we raise the handle of that, the honey will run, and no small matter will clog it up. The comb-basket was too small for my frames. A clean frame, with no comb built on top or sides of the frame, would

fit first rate. Those were my objections. I make the same machine, but make the can one inch deeper and one inch wider; comb-basket (wire cloth, three meshes to the inch) one inch deeper and one inch wider; and put in a two inch gate. We like the Chapman machine the best for our work of any we ever saw; but if I make them I can make them to suit me. We make for our own use only, and don't make to sell.

E. FRANCE.

Platteville, Wis.

Friend F., you have given us an excellent summing-up of the cost of liquid honey. You say, however, the past season has been an extra good one. Now, it is quite likely that, during a poor season, the honey might cost as much as you get for it. In that case, however, you will have your salary for yourself and son, which is worth something. I don't believe it is time to stop until the cash out exceeds the cash in. In that case you would have nothing at all for your year's labor, and, of course, there must be retrenchment sooner or later, or else a winding-up of the business.—You make a point in regard to the honey-extractor, friend F., that is worthy of notice. If wire cloth with only three meshes to the inch, instead of four, such as we use, answers every purpose of an extractor, I should think it would be preferable, because the honey would pass out more freely. Is it not true, however, that there is more liability of the wire cloth sinking into the combs?

MY BEE-STING THEORY.

W. F. CLARKE'S REPLY.

FAR be it from me to "take it unkindly" that friend Savage or anybody else should "question the scientific accuracy" of my bee-sting, hibernation, or any other theory, especially when it is done in a vein of good-natured pleasantry. In fact, I rather enjoy that sort of thing. But I fail to see how the title, "Bees vs. Beavers," applies to the subject in hand, for I do not know of any antagonism between these two industrious races. There is resemblance in some respects. Bees work like beavers, with unflagging industry and indomitable perseverance. Perhaps, also, they work like beavers in making use of their tails. But this is the point in dispute, not between bees and beavers, but between bee-keepers like friend Savage and myself.

After a quotation which sets forth my theory in part, the writer says, "Now, I wish to know whether any company of bee-keepers would receive, without question, such speculations." Well, I hope not. I should be very sorry to have any thing of the sort received simply on my *ipse dixit*. Not even religious teaching is to be thus received. The ancient Bereans are praised as "more noble than those of Thessalonica," because they did not give an unquestioning assent, even to Paul's preaching, but "searched the scriptures daily whether these things were so." This is the proper attitude of mind in regard to the entire circle of human knowledge. When any thing is received as apicultural truth, because Cook or Heddon or Doolittle, or GLEANINGS or Clarke says it is so, we come to the mental slavery which leads people to believe because the priest or minister says so. Away with all this hu-

miliation of mind! I want nothing of mine received unless it commends itself to the reason as having the stamp of truth upon it.

Friend Savage asks, "Is the latter end indeed the 'business end' of the bee?" That is no speculation of mine. It is a common remark about the bee, that the sting end is the business end of that insect. I did not invent this phrase, claim no patent on it, and suppose it will continue to be in vogue even if my theory about the use of the sting as a trowel be shown to be a mistake. Properly speaking, both ends of the bee are business ends, and so also is the middle a place of business. The bee is constructed for business all over.

Perhaps I have too readily assumed that it is the formic acid which imparts to honey its keeping quality. Certainly I have regarded that as one of the fixed facts in apiculture. The honey stored by the stingless bees in Central and South America has no formic acid in it, and will not keep. Friend Savage writes as if the formic acid were a foreign and poisonous element in honey. Is that so? Is not its total absence, or its presence in too small quantity, a source of trouble with honey that is extracted before being partially or wholly sealed over? If normal honey must have some infusion of this acid in it, then surely we are not warranted in assuming that it is injected only when bees are angered. Admitting this, we must believe that they inject what is required "amid the sweet satisfaction and exceeding joy" with which they pursue their "unmolested avocations" within the hive. I have not said a word calculated to "create a fresh terror and panic" in the public mind as to the adulteration of honey with a poison. There is a trace of prussic acid in some fruits, in all stone fruits, if I am not mistaken; but I don't see any thing in this to create "terror and panic." Nature has a wonderful alchemy, and uses, in minute quantities, elements that, in larger supply, are known to be poisonous. Honey is not "evermore unsafe" because "poisoned by the bees themselves at the fountain head." It is not poisoned by the minute portion of formic acid given for the purpose of flavoring and preserving it, any more than all the tinctures of the druggist are poisoned by the alcohol put with them to preserve them. Exaggerated truth is one form of falsehood.

I do not propose at present to go into any proof of my theory. All I have said is, that my observations and reflections have led to the formation of an opinion which I have given to the bee-keeping public for what it is worth—much, little, or nothing. I am not a microscopist—the more's the pity; but I have seen many drawings of the bee-sting, and quite understand that it is as Ernest describes it, with a single exception. It is a "fine-pointed instrument like a cambric needle," in shape only, but very unlike it in texture, being remarkably flexible and elastic, quite capable of being twisted and curved to and fro. Used along with the *tarsi*, two soft fine hairy brushes, one on either side of the sting, I do not see any mechanical objection to its being utilized in the way I have suggested. Neither does Ernest, apparently, or he would point it out. But as to the offices of the sting in curing the honey or capping the cells, he has nothing to say, either pro or con. Perhaps he will, after further investigation. I hope he will, and others also. I do not know why tongue and mandibles may not aid the sting and *tarsi* in the offices referred

to, giving a joint co-operative action of both business ends of the bee. And if friend Savage can extract any more fun out of my speculations, it is all right; only I think he should back up his supposition with something based on observation and reflection in regard to the habits of the bee.

WM. F. CLARKE.

Guelph, Ont., Can., Jan. 7, 1887.

ELLISON'S VISIT TO THE S. C. STATE FAIR.

THE POISON OF BEE-STINGS, ETC.

I HAVE taken your advice, "Write only when you have something to write about." Well, I have been to our State Fair; and, more than that, I have been an exhibitor. At first it looked like a big undertaking to me. I have been a "honey-man" and queen-breeder for ten years, and this is the first that I have been able to get away from home at this season of the year, my health not permitting. I can assure you it was pleasant to meet so many birds of the same feather as flocked together there. Many whom I had well known from their writings and theories, I had a very nice time exchanging opinions with, as to the different modus operandi of getting the most honey, the best bees, etc. Of course, we have not as yet such an extensive premium list as you have in the North. There were only five premiums given by the agricultural society. I got three; viz., for best comb honey, best extracted honey, and best Italian queen. The latter I value most, as I boast of raising the best kind of Italian queens. I had your Simplicity hive there also, but the premium on hives was given to friend Fooshe, of this State, who exhibited one of the same kind. I had, besides, smokers, veils, wax, and a Novice honey-extractor. I tried the plan of cutting up sections and selling pieces at five cents each, but found it did not pay well. We have but few bee-keepers in our State who use the movable-frame hive, and a great deal of injury is done to the honey-trade by box-hives and their owners.

THE EFFECT A BEE-STING HAS ON SOME SYSTEMS.

A few weeks ago my wife was stung on the foot. In a few moments she was covered from head to feet with a scarlet rash, very much like scarlet fever. She complained of violent pain in the chest, and a dreadful feeling of suffocation. We placed her feet in hot water, and gave her a large dose of bromide of potash; and after an interval of an hour we repeated the dose. She was very ill for two days from the effects of the poison. One of my boys is affected in the same way when he is stung. It would be a great boon if some of our bee-keeping fraternity who belong to the medical profession would study a remedy for cases of this kind, and give it to us. Some say the poison is formic acid. We will say, then, if an acid, use an alkali as an antidote; but how many have used soda, ammonia, etc., for stings to no purpose!

I should very much fear the consequences if either my wife or little boy were stung by more than one bee at the same time.

REVERSIBLE FRAMES AND HIVES.

I have been compelled to think, that, if you can adopt them in the North, your bees do not use so much propolis as ours do. Even with the Simplicity hive, right side up, I find great trouble to lift the

upper story off, on account of its being gummed down so fast.

I am sorry to hear of the bad state your bees are in on account of foul brood. I don't know whether you have tried saving fertile queens in cages with a dozen or more of their own bees placed in the center of a large colony, or not. I make the cages by partitioning off a wide frame, and placing a bit of honey in the comb in each for food. You can then hang it right in the hive, and in summer it is good for two or three weeks. I don't know what you can do with it in your cold winters.

W. J. ELLISON.

Stateburg, Sumter Co., S. C.

I am not so sure that the friends in the North will like reversing any better than you do. It is a matter that is not yet decided.—We have tried caging surplus queens in the hives during cold weather, in the way you describe; but from the severity of the weather here, the queens so caged died in a week or ten days at the most.

BLACKS VERSUS ITALIANS, AGAIN.

MR. FRANCE COMPARES THE LARGE REPORTS OF E. J. BAXTER, AND OF P. H. FELLOWS.

ON page 52, 1887, Mr. E. J. Baxter, of Nauvoo, Ill., claims to have an apiary of Italians that beat the record of my student (Mr. P. H. Fellows, of Brodhead, Wis., whose report for 1886 I find in GLEANINGS, page 74). Well, Mr. Baxter, you obtained more honey, it is true; but you went back to the fourth crop to find it. That is all right. But do you *know* that the Italians did any better than the blacks would have done in the same location, at the same time? According to your own statements, your bees had a great deal better chance than those of Mr. Fellows. First, your bees were very strong, by your help, at the commencement of the honey-harvest. So were Mr. Fellows' bees. So far you are even. But now turn to Mr. F.'s report, page 74, and you will see that his honey was all extracted between May 29th and July 6th—a period of 38 days, while your harvest commenced the middle of June and lasted until the 20th of September—a period of 97 days, or 21 days more than double the time that Mr. F. had. Even then you secured only 80 lbs. more on an average per colony. You did not increase your stock. Mr. F. raised 32 new colonies. You had 63 surplus-boxes with frames full of empty combs—about a set and a half of empty combs for each colony. Mr. F. had none. You used full sheets of foundation, while Mr. F. used only half-inch strips—just enough for a guide. Lastly Mr. Fellows had the long-to-be-remembered drought of 1886 to contend with, while you have gone back to a more fruitful season. Now, I don't see where you can claim any superiority for the Italians, in comparing those two records. I believe the blacks would have done just as well under the same circumstances. It simply proves my statement, that the location and the man have more to do with success than the race of bees.

But it is my candid opinion, that a half breed between the Italians and the blacks is better than either race pure. They may do a little more stinging, but I can handle any of them.

E. FRANCE.

Platteville, Wis., Jan. 24, 1887.

BLACKS AND ITALIANS.

ALSO SOMETHING ABOUT THE DESTRUCTION OF
EXTRA QUEEN-CELLS.

I NOTICE in GLEANINGS that quite a number are talking about the black and hybrid bees being superior to the Italians as honey-gatherers. This may be so in some localities, but not in mine, of which fact I was convinced last season. I keep in my apiary two colonies of pure black bees, and had a very good opportunity of testing them as honey-gatherers beside my Italians.

About June 20, 1886, the white clover failed, on account of the drought. Now for the result: The Italians switched off on to red clover, and worked from morning till night, while the blacks were trying to rob. For some reason, the window to the honey-room was left open, and the bees swarmed in by the hundred. I closed the window to keep out those that were out, and darkened the room all but this window. In a few minutes the bees in the room were all on the window, perhaps two hundred in all, and not one had a band. Now, friend R., why should so many black bees come into this room, and no Italians, if the blacks were as good honey-gatherers as the Italians?

Does the newly hatched queen tear down the unhatched cells? Yes, the young or first queen hatched will bite a hole in the unhatched queen-cells, and bite and pull the doomed queen to death. This I saw last season, with my own eyes. L. J. TRIPP.

Kalamazoo, Mich., Jan. 17, 1887.

Friend T., the question of blacks and Italians has been discussed over and over for perhaps twenty years past, and I think there is no question but that the rule is as you give it. There are also occasional exceptions, owing, perhaps, to peculiar circumstances; and of late we have been gathering up these exceptions, and it is quite likely that hybrids many times produce more honey than either race pure, especially *comb* honey. It has also been abundantly proven, that the young queen herself bites a hole in the side of the unhatched queen-cell. As to whether she pulls the unhatched queen out, or whether the workers do it, is not so well settled. The workers some times assist in tearing the cell down, for I have seen them do it.

UNITING BEES, AND ALL ABOUT IT.

WHEN, WHY, AND HOW IT SHOULD BE DONE.

NOTHING is simpler, if the process is properly understood. I am perpetually surprised at the cumbersome methods practiced by some old bee-keepers. If done properly, I see no occasion to cage the queen if she belongs to either one of the colonies united. I have never lost one yet that I wanted to keep. If each colony has a queen, either one of which you are willing to sacrifice, pay no attention to them. One will die, the other survive. If there is only one, naught will hurt her: she is as safe as any queen in the bosom of her own family. You will generally find this to be the case, even though the bees may do some fighting; always, in case they do not. As a rule, bees can be united in safety any time when other bees are not

flying. The only case in which I have known the rule to fail is during a dearth of honey in hot weather, when I find they will sometimes fight considerably. There are cool cloudy days in spring and fall, any time during which the uniting can be done. Generally, however, it is necessary to do the work early in the morning or in the evening. Evening is the best time. Bees manipulate better then than in the morning, and they are more apt to stay in their new quarters. Unite contiguous colonies if convenient, but you may unite one with another anywhere in the apiary if you have reason to do so.

Some time in the day, remove about half the frames from the two hives. Then in the evening set a hive near where you want the colony to stand, and put into it a frame alternately from each hive. This mixing-up is the very best way to make the astonished and mystified little things form the acquaintance of their new home and each other. If you do not in any case want to use all the frames in the two hives, shake the bees from the extra ones on a sheet or wide board in front of the hive, fixed so that they can crawl readily into it. If the two colonies are very far apart, set your empty hive near one of them and simply carry the frames from the more distant one to it. If the work is done in the evening, very few (often, I think, none) will ever return to the old stand. Those that do will distribute themselves among surrounding hives, in case you remove the old hive. To load the hive of bees on to a wheelbarrow, and take a run to the stand of the colony with which you want to unite, in order to get the bees stirred up, as directed by Mr. Doolittle, may be a good expedient; but it is a harder way than mine, and by no means necessary.

WHEN AND WHY.

The when and the why are interdependent. The reasons for uniting are not always the same in all seasons. There is, however, one ever-present reason to one who runs for honey chiefly; viz., to prevent undue increase of stocks.

UNITING IN THE SPRING.

I do not favor that plan very much. If you want to diminish the number of your stocks at that time, it will do. In case one's capital and stock of fixtures are limited it is sometimes well to do this. It is seldom profitable, I think, to unite weak colonies in early spring, except in case of queenlessness. Pack them up warm and dry on three to five frames; set the hive in the sun, and half a dozen of them are as apt to pull through as that one would if they were all united into one. Inmates of weak colonies are generally weak from dysentery, or are in some way unhealthy. Uniting them stirs them up and causes them to move out and go to work. Their puny energies are unable to stand the drain upon them, and the bees die off much more rapidly than if left in quiet, and they dwindle down to another weak colony before the honey-harvest commences.

UNITING IN SUMMER.

Mr. Doolittle practices uniting weak colonies at the beginning of the honey-flow. I think I know a "kink" worth six of that for most localities, if not for his. I hive the first swarm that issues on the old stand, and set the old hive off. In the evening of that or some early day I carry the frames of brood and adhering bees to one or more of my weak colonies, and in a few days they are ready for work. Where they will swarm all through the honey season, this is much the best plan.

UNITING IN THE FALL.

To a bee-keeper who winters out of doors, one of the best safeguards is to have every colony well packed with bees. I usually reduce my stock one-fourth to one-third. There is another reason for this. Brood combs are ever accumulating out of proportion to our desired increase of stock, while we are still wanting many pounds of *fdn.* every year. Hence we must cull out and render into wax all imperfect combs. Drone combs, crooked combs, combs filled with pollen, etc., all are condemned to the wax-extractor. Look over your stock late in September or in October; and all such frames, containing brood, put behind a division-board until the brood is hatched. If you want to unite any stock with another, insert those frames behind the division-board of that other colony. The latter may be thus strengthened at different times, while the two that are drawn from may be united at convenience. I often divide one colony between two others by means of frames. Or I sometimes shake the bees off in front of a colony containing its full or nearly full complement of comb, and give most of the frames to another. Of course, these processes may be modified to suit the wishes of the apiarist. I neglected to observe in the proper place what will occur to every one, that uniting in the fall helps us to weed out inferior queens. Autumn is the best time to do this culling, as a rule. GEO. F. ROBBINS.
Mechanicsburg, Ill.

BROERS' REPORT.

DOES THE COLOR OF HIVES MAKE ANY DIFFERENCE WITH THE BEES?

FRIEND ROOT:—As the honey season is past, and I have had time to figure up results, I will proceed to send in my report. I started in the season of 1886 with 24 colonies of Italians and hybrids in fair condition; increased by natural swarming to 39. I sold and doubled the rest of them back to 24, and fed to keep from starving. One colony deserted in May. I took in all a grand total of 240 lbs. of honey, about one-half comb. I got six swarms in September from the 11th to the 24th, making in all 29 colonies in the fall, in good condition. I sold 5 colonies in the fall, which leaves me 24 to begin another season with.

ARE BEES COLOR-BLIND?

I will give you an item right here which goes to show that bees are not color-blind. I gave my brother a colony of bees; and as he had a hive of his own I just took the frames and bees from my hive and placed them in his. Jan. 12 we moved them over to his place, about 150 yards distant; and as the weather remained too cold for bees to fly, for about a week after moving, of course they could not come back; and to prevent trouble I had moved their old hive about 15 feet away, and cleaned off their old stand so they would not return to it. When the weather did turn warm, a great many of the bees returned; and on going out next morning I was surprised to find about 50 bees that had found the old hive, although it was placed among a pile of other hives all painted white, except that the hive referred to had the portico trimmed with blue. The poor little fellows had clustered in the portico, and some few had gone inside the hive; and they were as forlorn a looking lot of bees as I ever saw.

ROBBING, HOW TO PREVENT.

A plan that works well with me is to throw a sheet over the colony being robbed; and if the robbers are mostly from one colony, throw a sheet over that also, and just see how quickly they will change their tune. Leave the sheet on the robbed colony until after sundown, and then contract the entrance so it will admit only one or two bees at a time, and they will protect themselves by morning, if they have a good queen. If they have not, unite with some colony that has. M. BROERS.

Gonzales, Tex., Jan. 25, 1887.

REPORTS ENCOURAGING.

WIFE AND I: \$360.35 CASH FOR THREE MONTHS' TIME WITH THE BEES.

WHEN I received GLEANINGS for Dec. 15th you said you would take the liberty of sending it, etc. We are very glad you took that liberty. (By saying *we*, I mean wife and I, for we are partners in the bee-business—and, by the way, I do not believe any man can keep bees successfully without a good wife to help him). Here is our report for 1886:

May 1, 40 swarms; sold 6 (without hives) \$30.00; sold 13 (with hives) for \$65.00; sold honey, 3000 lbs., for \$330.00; total, \$425.00. Our honey is all sold now. Bought 25 Simplicity hives, ready for use, except painting, \$50.00; 3000 sections, 9.75; 9 lbs. *fdn.*, \$4.90—a gain, in one year, of \$360.35.

We have 56 swarms in the cellar now; wintered last winter without any loss whatever. We spent about three months' time altogether; peddled most of the honey, and got cash for it, 10 to 12½ cents. I never saw a section of honey until I produced it four years ago. What success we have had we owe to A. I. Root. We have taken GLEANINGS, and have had his A B C book and no other.

E. R. A. & B. BRAINARD.

Postville, Ia., Dec. 27, 1886.

AN AVERAGE OF 95 LBS. PER COLONY.

Bees are in fine order for winter. This year the average number of pounds of honey per colony was 95; but little is sold up to date.

THOS. H. TRICE.

New Providence, Mont. Co., Tenn.

FROM 35 TO 55, AND 3000 LBS. OF HONEY.

I commenced the season with 35 swarms—20 good ones, 10 poor, 5 very poor. I increased to 55, and made 3000 lbs. of cap honey, very little basswood. Besides this I have more than enough natural stores to winter on.

WM. P. ABEL.

Vienna, Oneida Co., N. Y.

FROM 39 TO 52, AND 1100 LBS. OF HONEY.

The season has been a poor one. Basswood was a failure. I took 1100 lbs. in 1-lb. sections from 39, and increased to 52 by division during goldenrod bloom. Each has from 15 to 20 lbs. for winter. I placed them all in my bee-cellar Nov. 13. The temperature was 50, and they seemed to be very quiet. There was an average shrinkage last winter of 9 lbs. in 42 colonies in the cellar from Nov. 1st to Apr. 15th—165 days. Temperature was about 50.

N. A. BLAKE.

Smith's Mills, Quebec, Can.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz. *Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room.* We have also *Our Homes, Part I. and Our Homes, Part II.* Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

CONDUCTED BY ERNEST R. ROOT.

THE BOYS' AMATEUR BEE-HIVE FACTORY.

THE bench-vises, which you remember the boys sent for, were duly received. They were now fully equipped to make any thing which youthful geniuses can turn out. After school, during evenings, Mr. Green taught the boys in the rudiments of carpentry. He showed them how, by the use of a try-square, they could make every thing perfectly square. By practical examples, he instructed them as to the mortise and tenon, rabbet, dovetail, and miter. The latter, he said they would often have occasion to use. He then made them a miter-box which he explained as being so useful in a good carpenter shop. The keen zest and enjoyment with which the boys took hold of the work made them apt scholars, and they soon became quite proficient in the use of tools. In the mean time Mr. Green had loaned them a copy of the *A B C of Bee Culture*, and had directed them to read carefully the chapter on *HIVE-MAKING*, which the boys did. Though the instructions there given were designed to accompany the buzz-saw, they thought they could make use of some of the instructions, even for hand-tools.

One evening after school, while the boys were talking and planning in their workshop they discovered that they had insufficient light. Jimmie proposed to Sam that they make a little window just over the work-bench so they could have "lots of light" just where they wanted it. Sam readily agreed, but said he must first ask his father's permission to cut a hole. When the boys presented the matter before Mr. G. the latter readily consented, and at the same time explained how it could be done.

A pane of glass, 10x15, was purchased. An oblong hole was made through the side of the barn, one-quarter inch smaller all around

than the glass. This was ingeniously let into the wood and then held there by strips of wood nailed around the edge of the glass.

Finally Saturday, which was a good while coming to the boys, arrived. They had previously had some experience in making one or two hives, and now they felt confident that they could make a larger number without so much waste in lumber as in the first. Mr. Green had given them a little talk on the division of labor. He explained how it would be economy of labor and time to make several hives at once. Accordingly the boys had decided to make a "batch of six hives." The first thing to be done was to saw the boards up in proper lengths.

When they had been sawing for awhile, Jimmie exclaimed, "By cracky! this is mighty tough work." As he said this the perspiration began to stand out on his nose, and his arm and back began to ache. Straightening up and throwing back his shoulders he said, "This is more work than play—almost as bad as sawing wood."

"You are right," said Sam. "Sawing hives with these little saws is too hard work."

"I'd just like to shake hands with the man who invented the buzz-saw. Say, Sam, don't you s'pose we could get up one?"

"A small mandrel that would answer our purpose would cost only \$2.25, and a couple of small saws could be had for about \$1.50. I don't know how we could get the power."

"Why can't we make a windmill? We've made little ones," said Jimmie.

"So we could!" said Sam, brightening at the idea. "Let us talk with pa about it."

The boys commenced work on their hives again with renewed energy.

That evening the matter was brought before Mr. Green. After some reflection he thought the boys might manage to make a windmill for running a buzz-saw for light work; but then they would need his assistance. It would have to be quite large to run a buzz-saw—considerably larger than the boys had ever made. He advised them to wait until he could talk to a friend who was a machinist.

(Continued.)

JUVENILE LETTER-BOX.

"A chiel's amang ye takin' notes.
An' faith, he'll prent it."

A LITTLE GIRL WHO "BEAT HER PAPA ALL HOLLOW."

My papa gave me some bees. They have made me 67 lbs. of nice extracted honey, and I traded my honey for a nice bat and a wax doll. Papa says my bees beat his all hollow. MAMIE BROERS.

Gonzales, Texas, Jan. 2, 1887.

Thank you, friend Mamie, for your report. We have known your papa real well, and we are glad to know he has a little girl, even if she did beat him all hollow.

A LITTLE GIRL'S REPORT IN REGARD TO THE BEES GATHERING POLLEN IN TEXAS.

This is the third letter I have given you on the subject. In 1885 they commenced bringing in pol-

len on Sunday, the first of Feb. In 1886 they commenced on Sunday, the 31st day of Jan. In 1887 they commenced on Saturday, the 22d day of Jan. Our earliest bloom is the water-elm tree. It is very white pollen. Bees are all healthy and strong to date. Papa has sixty colonies; not one has died.

LIZZIE L. MULLIN, age 11.

Oakland, Texas, Jan. 24, 1887.

VESTA'S LETTER.

My mother has 20 hives of bees, and she puts them in the cellar in the winter. She had 10 hives last spring, and got about 400 lbs. of honey in two-pound boxes. What the bees don't finish up we extract. My sister and I turn the extractor. Ma sent to Mr. Root for the extractor two years ago. Last week Thursday it rained so hard I could not go to school, and I tacked muslin on to the frames for chaff cushions to put over the bees.

Last summer my Sunday-school teacher gave me a Bible for learning perfectly the ten commandments. When I had them learned we found that my little sister Frances, seven years old, had learned them just by hearing me say them. We are in the same class, so our teacher gave her a Bible too.

Owego, N. Y., Nov. 27, 1886. VESTA PADGETT.

BANKING UP SNOW FOR WINTER PROTECTION.

My brother has had pretty good luck with his bees, as he has not lost one swarm this winter. The way he keeps his bees in winter is this: He puts boards up around the hives so as to keep off the wind, and when it snows he shovels the snow up all around the hives, but leaves the entrance of the hive open, so that they can get air. He says that this warm weather is hard on them, for they go out and try to fly around, and the snow blinds them so they can not see, and they freeze to death. He built a shed for them last winter, and they did not do so well, for he had 36 stands and lost half of them. He likes to work with bees, and he likes the honey also. He has now 52 stands of bees, and he has been talking of buying some more of one of our neighbors, who wants to sell them. He made a great deal of money selling honey last summer, and, besides, he kept enough to use, and he kept enough to use all winter. ROSE CUSTIS.

Gillem, Ills.

I hardly think the bright snow blinds the bees so that they die from the effects of it. Bees flying out on these warm days are liable to become chilled. If they once alight in the snow they scarcely ever rise again. It is the chilling and not the blinding them that plays mischief with our pets.

JUVENILE SWARM-CATCHERS.

My pa has 54 stands of bees in the cellar. We had 32 colonies last spring, and got 1200 lbs. of honey, and increased them to 52. I like to help work with bees. I help to tend them in swarming time. I watch them and catch the queen, and put her in a cage and lay the cage in front of the hive and let her be there until the bees come back; then I let her out of the cage and let her run in the hive. We have our queens all cropped. We have had a cold winter so far. The thermometer was down to 26 below zero on the 7th.

AARON A. KNOLL, age 12.

Salamonia, Ind., Jan. 17, 1887.

Boys and girls make capital swarm-catchers, don't they, friend Aaron? Papa can

not always be on hand when a swarm issues. Instead of running to tell him that the bees are swarming you can tend to them yourself. Little boys and girls, you can all do it if you will only try. I was "awful 'fraid'" when I first tried it; but the offer of a whole dollar made me bold, and I succeeded, as some of our old readers may possibly remember. After that I did not have to be hired to catch swarms when "my pa" was away. That was ten years ago. If you wish to know more about it, see last pages of the A B C of Bee Culture.

OUR FRIEND CHARLIE ASKS SOME MORE QUESTIONS.

We commenced in the spring with 8 colonies—5 in box and 3 in L. hives. I increased to 20 by swarming. The box hives did nearly all the swarming, while the Langstroth hives made the honey. We got only 2 swarms from the frame hives. The box hives made but very little honey. We took 300 lbs. of comb honey. This was a good season for bees. It opened up April 17, with the blooming of golden willow. This, although lasting but a short time, produced lots of honey; and during its blooming, bees filled their brood-chambers. Locust also produced a great deal of honey this year. Basswood yielded lightly on account of rains; but white and sweet clover lasted for several weeks. Red clover produced some honey during its fall bloom. Honey came in so plentifully all summer that we could work with the bees any time in August without any danger of robbing. Drones remained until after the middle of August.

How long can our bees be confined in winter without being troubled with dysentery? Are any of the bees destroyed that are out at work during a heavy rain? Will a little clover chaff mixed with wheat chaff draw dampness? In swarming, will bees always cluster up in a tent that is set over them? What part of the spring is the best time to Italianize? CHARLIE L. GREENFIELD.

Somerville, Butler Co., O., Jan. 3, 1887.

With favorable conditions, friend Charlie, I think the bees may be confined four or five months, without any trouble whatever. Where the stores are not of the best kind, however, it may be quite desirable to give them a fly every three or four weeks. I presume some bees are lost during a heavy rainstorm that comes up suddenly. If the sun comes out shortly afterward, however, I believe they usually dry off and get home.—I do not think that clover chaff would do any harm, and I think we have had reports where bees were wintered nicely with clover chaff and nothing else.—We have never tried controlling swarms by setting a tent over a hive after the bees have started to come out. I presume they would cluster somewhere on the tent.—The sooner we Italianize our bees in spring, the better; but the weather, however, would probably make it uncertain business before the latter part of spring, in our latitude.

BEEES ALL RIGHT SO FAR.

My papa has 120 colonies of bees. He has part of them in the cellar. The thermometer stands about 34 degrees down cellar. The bees seem to have wintered all right so far. They seem to be very quiet. That is a sign they are wintering well. It is not very cold here now. The thermometer is 50

to-day outdoors. Papa's bees are in chaff hives. He packed them with cut straw. Papa hived all of his bees double to keep down the increase, except one swarm which he put in the new Heddon hive last summer. Last year was a poor season. We got but a few hundred pounds of honey.

LUCY HURLBUT, age 11.

Linden, N. Y., Jan. 22, 1887.

A BOY'S REPORT FOR THREE YEARS.

I commenced bee-keeping in 1884. Pa had a man hired to cut brush, and one day I went down where he was at work. He went to take a drink of water, and he saw a swarm of bees in the tree. He gave them to me, and I put them in a cracker-box. I watched them all summer, and that winter Mr. Hall went down to New Orleans to the Exposition, and he bought a 9-frame Langstroth bee-hive. That winter I would look at them about every two weeks. When spring came they were all dead. That was the first lesson I learned.

In the spring of 1885, Mr. Hall and I bought 3 hives of bees, and we took 15 lbs. of honey from one new swarm. I increased to 8 colonies, and in the spring I had 6 colonies of bees. In 1886 I increased 15, lost one; two got away; and I caught one. I took 50 lbs. of honey from one hive which did not swarm. I divided one swarm, and sent and got an untested Italian queen for \$1.00, which did well. I have now 14 colonies of bees. This evening Mr. Hall found a colony of bees in the hedge. He said there was about half a bushel of comb, and the bees are dead. Did you ever hear of bees settling in a hedge?

PAUL M. FRANCIS, age 14.

Mulberry, Bates Co., Mo., Dec. 13, 1886.

It doesn't pay to tinker with bees during the winter, does it? Old veterans sometimes manage to do it without killing the bees; but boys and beginners had better let them alone.—Bees frequently do swarm and cluster in hedges, but I never before heard of their being found in such places at this time of the year. No wonder they were dead when they were found; that is, if you are having as cold weather as we in Ohio have been having.

TOBACCO COLUMN.

SHALL GROCERS SELL TOBACCO?

I WISH to say to you, that I have prevailed on my brother-in-law to agree to give up the use of the filthy weed, tobacco; and he says that, if you will send him a smoker, if ever he takes to the use of tobacco again he will pay you double price. He keeps bees. Having just read Terry, in GLEANINGS, on the use of tobacco, I must ask you a question, though I know what your answer will be. I am 61 years old; have never used a bit of it in any shape, except to smoke seed-ticks with it, to get rid of them. Well, I have a little one-horse store, and the country is flooded with stores. All sell tobacco. I have to sell it also, against my will. I have tried to prevail with the young to give up the use of it, telling them I would quit keeping it. The answer is invariably, "We will go to other places and get it, and you will lose our custom." What am I to do? To quit selling tobacco is to quit business.

CHARLES L. GOUGH.

Rock Spring, Mo.

Friend G., we have had just such a case in our own town. A young man owning a grocery became a Christian. He thought it his plain duty to give up the selling of tobacco, although the profits from his sales of the weed were large. Some of his former customers did go to other grocers for their tobacco and provisions; but in spite of this, and in spite of the fact that there are seven other groceries in our village of a little over 1500 inhabitants, his business has prospered, and his grocery store ranks among the two or three of the kind in town that are doing the most business.

HAS CONQUERED THE HABIT.

I promise never to use tobacco any more. If I do I will send you 70 cts. for the smoker. If you see fit to send me the smoker, I shall keep my pledge.

Pawlet, Vt., Dec. 14, 1886. S. H. HARRINGTON.

If my husband uses any more tobacco, I will see that you have the 70 cts. for the smoker.

MRS. S. H. HARRINGTON.

Here is what friend H. says after giving up the use of tobacco:

The smoker is nice, and I am much obliged for it. It was rather hard to go without tobacco at first; but, thank the Lord and you, I have conquered.

Pawlet, Vt., Dec. 28, 1886. S. H. HARRINGTON.

Many thanks for the smoker you sent me; if I ever use tobacco in any way I will pay for the smoker. I received your A B C, and am highly pleased with it.

W. C. SWETNAM.

I am a reader of GLEANINGS. I have been a chewer of tobacco for 40 years. I wish to place myself under bonds to discontinue the practice, for which send me a smoker.

I. A. PRESNELL.

St. Louis, Mo., Dec. 29, 1886.

I gave up the use of tobacco last spring, and haven't used any since. If I am entitled to a smoker, send it along. If I begin again, I will pay for smoker.

FRED ELDRIDGE.

Sharon Spa, N. Y., Jan. 3, 1887.

W. C. Sweasman says he has quit the use of tobacco; and that, if you are willing to send him a smoker, you may do so; and if he ever uses the weed again he will pay you for the smoker, postage and all. Send it to him; and if he breaks over I will see that it is paid for.

A. T. DOYLE.

Berthaville, Mo., Dec. 28, 1886.

TWO GIVE UP THE HABIT.

Here is another party coming, pledging themselves to henceforth abstain from the use of tobacco, if you will send them each a smoker. Should either of us hereafter use it in any way, I will pay twice the price of smoker or smokers.

J. A. AND H. A. KIME.

Fairfield, Pa., Jan. 1, 1887.

INCREASE IN WEIGHT AFTER GIVING UP TOBACCO.

My father is now 74 years of age, and has not used tobacco for 2 years. He had used it for 52 years. His average weight when using tobacco was 150 lbs.; it is now 195. He promises never to use it again, and asks you to send him a smoker. If he ever uses it again he will pay you for the smoker.

JOHN C. PIERCE.

Groton, Vt., Jan. 2, 1887.

OUR HOMES.

When a man's ways please the Lord, he maketh even his enemies to be at peace with him.—PROV. 16: 7.

NOW, I am going to presume in my talk to you to-day, that we have enemies even in our homes. It is a sad thing to contemplate, but facts are often sad. I have particularly in mind the relationship existing between father and mother, and son and daughter; and if there is any relationship in this world that is sacred, it seems to me it is the relationship between parent and child. What does that have to do with the matter of enemies? Well, I suspect if Satan had never obtained a passageway into the human heart there might have been perfect peace and harmony under all circumstances, and for all time, between parent and child. Let me illustrate what I am thinking of, by a little chapter from my own experience.

I am one of seven children. There are three older and three younger. My past recollections of my mother are, that she was a hard-working, burden-bearing mother. Her trust was in the Savior always, but she had many trials and difficulties. In addition to the large family, we were at one time in rather straitened circumstances. Father was a carpenter by trade, and did not always get employment. At other times sickness threw him behind. I remember when affairs got to such a point that things really looked dark for father and mother and a family of seven, and that mother had been praying that God would open a way for father to earn an honest livelihood. The prayer was answered, but the conditions of it were that he should be away from home perhaps more than half of the time. This threw the management of the family upon mother. Now, father was stern and severe. He was of the old Connecticut type, and did not believe in sparing the rod. Every one of the seven, from the baby up, learned to obey, and a good many times they obeyed with fear and trembling. We obeyed mother also, but no child was ever afraid of her. If she punished, her loving hand was restrained by a loving heart from making the punishment any thing very much to be dreaded. When father was at home we obeyed her somewhat through fear of him, if we did not obey with alacrity; but when he was away, some of us fell into loose ways. I myself remember with feelings of sorrow my selfish and disobedient acts and ways; and when my elder brother was away I was the eldest boy in the household, and my services were much needed. But I got lazy and listless about getting up mornings. My mother would call me twice, and sometimes the third time, but I didn't get up then until I got ready. I was also in the companionship of bad boys more or less—boys I shouldn't have been with had my father been at home, and from them I learned examples of disobedience. A neighbor would call one of the children two or three times. The chil-

dren, without making move to obey, would "sass back," as we boys used to term it, in an undertone. The conversation might be something like this:

"Charlie, I have called you three times; now come here *this instant*."

Charlie replies in an undertone, "Well, suppose you did call three times—who cares?"

At this the other boys would titter and laugh, which incited Charlie to further acts of disobedience. By and by Charlie would get whipped for bad behavior. When he came back he would have over something like the following:

"Scolding don't hurt any, whipping don't last long, and kill you they dare not."

Now, friends, I never did as badly as the above; but I might have done so had I had the same kind of training and encouragement in badness. I can not remember positively, but I presume likely my mother used to speak something like this:

"Amos, I have called you three times now, and you really must get up at once."

I do not remember of ever talking back when my mother called me, but I do remember that I grumbled to myself, as I got up in a sullen way, "Well, suppose you have called me three times—who cares? and who wants to be scolded at and found fault with for everlasting?"

Of course, I got up surly. If the dog got in the way before my eyes were well open, I kicked him. If my younger brothers or sisters, who were up and washed, and bright and happy, half an hour before I was, came in the way, I felt angered at them. Perhaps I gave one of my sisters' dolls a kick. After I had been up a while these surly, peevish feelings wore off, and I was a tolerably bright happy boy, and most of the time we were a pleasant, happy family. But I am saddened to be obliged to admit, that sometimes the surliness seemed to be contagious, and got among several of us at once. We pained our tired, patient mother by wrangles and disputes; and when she exhorted us to godliness and loving-kindness to each other, we rejected her Bible and her religion. Now, mind you, we didn't often do this openly to her face, if we ever did. It was a sort of undercurrent; and had we been called to task we would have said, may be, we were "just in fun." Poor mother was sorely tried with many cares as well as fatigue, and it would be nothing strange if she sometimes forgot just a little, and reproached or complained, in a way that was not just the wisest. Dear father and mother, whose eyes are resting on these pages, have you never had any trouble by disobedience among the children? Have you never been tried to see them growing up selfish and indifferent? and have you never felt any discouragement, and felt that talking was of no use? May be you do not say it out loud, but did you ever feel, "I declare, I have talked and talked to that boy John until it seems as if there were not a bit of use in talking any longer. If the boy goes to ruin, he will have to go. I actually believe I have told him twenty times to put his muddy boots out on the porch; to hang up his hat, and to shut the stair door after

him. Just look there, will you? There are the boots on our best carpet; there is the best hat on the floor, and there is the stair door wide open, with such a draft through here that we have probably all caught cold. I have told him of it kindly and patiently; but if he does not say outright that he does not care, his looks say it plainer than words can speak it. What shall I do?"

Now, friends, am I not right in saying that enmity is growing up between this mother and son? Both parties are getting calloused and case-hardened, as it were. The mother has got to the point where she says if the boy goes to ruin, he will have to go—she can't do anything more for him. The boy has been so long disobedient, selfish, and unfeeling, that he can say outright, "Well, who cares if I did? what are you going to do about it?" Now, I don't mean to say that I got to be as bad as that, but I was growing stronger that way, and had got pretty well along. I knew my mother was overworked, but other boys' mothers were overworked also, and we couldn't be tied up to mother's apron-strings, so we laughed it off as a joke, and let it slide. I do not know how common such things are. You can tell, dear friends, better than I whether Satan has made any such inroads into your own loved home. I hardly need tell you that boys, when they get to the stage I have pictured, are ready for strong drink and games of chance. A cigar will come pretty soon, unless something interposes. Perhaps some tired mother or discouraged father feels like saying, "For God's sake, Mr. Root, tell us *what* we are to do when children won't obey us." Dear friends, it is with joy and gratitude to God that I undertake the task of telling you what to do in cases like these. It is with joy and gratitude that I tell you what saved me from—who shall say what?—and placed me here to write these Home Papers for the help and encouragement both of parents and children.

I do not know how old I was at the time—perhaps ten or twelve. A series of revival meetings was held in our town of Mogadore, Summit Co., O. I do not know what church was instrumental in starting the revival, for I did not go; I did not like "meetings." Mother went, I believe, regularly, and I heard something of the outpourings of the Spirit, as some of the brethren and sisters termed it. I did not know much about the meetings, and cared less; but this I did know: That a change had come over my mother. She was always a Christian, but now she was a happier and more hopeful Christian. It shone from her face, it rang out from the tones of her voice, and it overflowed from every act and motion of her life. I believe my mother in her younger days was a rather handsome woman; but as my memory goes back this morning it seems to me she was a beautiful mother under the influence of the outpourings of God's spirit into her heart. Notwithstanding her cares and the hard work that lay before her, she was at this time constantly breaking forth into snatches of those grand old hymns. Occasionally I woke up in the night and heard her voice in prayer. This was nothing new,

but just now the tones were hopeful and joyous. She prayed as if the blessing had already come. She prayed for my poor self, as if she *knew* I was going to be a better boy. We began to get *acquainted*, and it was about this time that she began to teach me and interest me in gardening; then she told me in a way that did not have any severe reproach about it, that father was having a hard time to get along, and that she and I together could help a good deal by having a nice garden. Poor mother! she was already doing more work than any human being ought to do, and yet she planned to help me make garden. Finally she spoke one evening about the trouble of getting me up mornings. She told me that, in father's absence, I was almost the man of the house, and that it would be a great help to her if I could get up in good season, or, at least, the first time she called me. She had struck the right chord, and I was disarmed. When a drunken man or a highwayman gets a revolver in his possession, the first thing to do is to disarm him; get out of his hands that murderous weapon, by hook or by crook; and, my friend, when Satan makes an inroad in your child's heart, the child must be disarmed—not by might nor by power nor by reproaches, nor by telling him that you have called him three or four times already, but by Christ's spirit; by throwing away bowie-knives and revolvers, or, if the expression is too strong, by throwing away reproaches and harsh feelings out of your own heart; you must do it in the language of our text:

When a man's ways please the Lord, he maketh even his enemies to be at peace with him.

I remember the very morning after this when mother called me. I remember the tones of her voice better than the words, but they were something like these:

"Amos!" She spoke just my name, and nothing more, until she had roused me to consciousness, so that I remembered the conversation of the night before. Then she said, in gentle, loving tones, "The sun is shining; you will get up now and help me, will you not?" I don't think I replied back, "Yes, mother, to be sure I will," but the look in my face said it better than words, and I was not only up and dressed quickly, but I was bright and cheerful. Mother had conquered—Satan was cast out, and that, too, in the name of Jesus Christ, just as Peter bade the lame man get up and walk; but mind you I had not accepted Christ at all; there was no thought of Christianity direct in my boyish heart. I got up for my mother. It was Christ's spirit that moved me, but I saw that spirit through her; and, dear parent, if your child is to be led to Christ it must be to Christ through *you*. When he can see Christ embodied in your daily life, then he will accept Christ. You may ask if there is no limit to this. God only knows where the limit is; but we read in his holy word (Lev. 26:8), "Five of you shall chase a hundred, and a hundred of you shall put ten thousand to flight." I can not remember that my mother had any trouble afterward, in getting me up mornings. Neither can I tell you how much we enjoyed the gardening

that summer; nor can I tell you how much father was pleased to go around with mother and to see how much things had grown during his absence. As an illustration of the change that came over her boy, I will mention a little circumstance.

Mother was the only one of the whole family who knew how to milk a cow, and in father's absence she milked the cow winter and summer, and oftentimes when the older ones sat around the stove. One stormy morning, I think it was when snow and sleet came with the rain, she started to milk the cow as usual. I jumped up and took the pail, saying, "Here, mother, you have milked that cow long enough."

She expostulated gently. "Why, Amos, you have not learned how. Let me milk this morning, and when we have more time I will teach you to milk, if you really want to do it."

Now, I had begun to have quite an idea by this time of being a man and being manly, so I took the pail from her with a good-natured smile. I told her that, if I did not know how to milk, I guessed I could learn. I had been taking care of our big red bossy, winter and summer, so that she knew me and I knew her, and there was not very much trouble on that score; but before I got the pail full I concluded it was a bigger job to milk a cow than I had ever supposed. I was ashamed to go back and tell mother, so I stuck to it; and, if I remember correctly, mother never milked the cow any more. I hardly need tell you that the experience of that winter and summer has had its effect on my whole life; nay, further: it has produced a marked effect on the lives of every one of those seven children. My poor father was not blessed with mother's natural helpfulness, but he seemed rather given to doubt and darkness. He once made the remark, that he should have had his name taken from the church records more than once had it not been for his wife. The good pastor to whom the remark was made, replied, "Brother Root, you may thank God for your good wife who has pulled you through so many seasons of darkness; and by his grace we hope she may yet pull you into the gates of the eternal city." And I believe the prediction has been fulfilled.

You may say, "But, Mr. Root, how are we to get that overflowing spirit of trust and faith? Must we go to revival meetings, and go forward, and get up an enthusiasm?"

I do think, my friend, you should make it a point to attend the revival meetings held in your vicinity; but besides this I think it is the duty of every Christian to attend the regular prayer-meetings as well as the preaching services; not only be on hand, but take up the cross and do your part. If you have met discouragements and trials, just such as I have pictured to-day, get up among your brothers and sisters and tell them you want to be nearer to Christ, and ask their prayers; and when you do this, be sure your daily conduct is in keeping; examine your own heart well, and see whether you are fulfilling the commands of the Scriptures. Read your Bibles, and see if they don't touch on the point of your

troubles. I told you about our friend Robert, in jail, a short time ago. Robert says he is a member of the church; he says he wants to be a Christian; but when I read those passages to him about loving our enemies, and doing good to those who hate us, he declared flatly, that, if that was what the Bible taught, he didn't want any of it. When it came right down to the plain teachings of the Bible, he refused to obey, point blank. Now, then, has your child seen you repeatedly love your enemies, and do good to those who hate you? When you get up in the prayer-meeting, and say that you are hungering and thirsting for an outpouring of the Holy Spirit, does every one who hears you say it know that you are complying with the conditions laid down in God's holy word? Another thing, that I know is helpful: Go often to your pastor; tell him your difficulties, and ask him to pray for you and with you. You may object, and say that he is already overburdened, and will not care to know about it. It is a mistake—it will help him in writing his sermons, to know the needs of his flock, and it will help him to talk over these things. You can not be a Christian and keep it all to yourself. No such baptism of the Holy Spirit would have been poured out upon my mother's life had she not been among God's children, and habitually gone around through the neighborhood in scenes of sickness and death.

The great point is, to get Satan out of your own heart, and the great danger is that you may be misled to thinking you are doing a Christian duty when you are almost wholly in the bonds of Satan. Beware of how you get into a set and formal way of reproaching the child over and over again. I once heard of a boy who was asked what his name was, and he replied that it was "Willie Dont." He was probably a boy of an inquiring turn of mind, and had heard it over and over so much, "Willie Dont," that he thought it must be his name. Sometimes a parent says, "Why, do you suppose a body can stop his work, and go and take time to have a long palaver with that child over some trifling matter?" My friend, the molding of the mind of the child, and the fashioning of a Christian character, is the most important work God ever gave to any human being to do. If there is any work in this world that is of any more consequence, let us hear what it is. Instead of standing at the foot of the stairs, and calling your child to get up, in hackneyed phrases that have been used over and over again, go patiently clear up stairs, no matter if you are wearied and in a hurry; stand by the child's bedside; wait until he is fully awake, then win good-natured acquiescence before you go down. Win him with Christ's love in your heart. Go up with a prayer and go down with a prayer, and yours shall be the victory over the schemes of the Evil One, and the victory shall be through Christ Jesus. And to him be all power and glory and honor for ever.

When a man's ways please the Lord, he maketh even his enemies to be at peace with him.—Prov. 16: 7.

NEW IMPROVEMENTS IN HIVE-MAKING MACHINERY.

SAW-TABLES, ETC.

AFTER Mr. J. S. Warner, our foreman, had got our new building with its new machinery nicely in running order he set to work to devise some improvements in some of our wood-working machines, to render them safer to the sawyer as well as to make them accomplish more and better work. Below we give you a view of one of the machines which he has devised and improved.

SAW-TABLE, WITH WARNER'S IMPROVEMENT.

This machine is for general-purpose work, such as we propose to send out. The improvement consists in having the distance from the ripping-gauge to the saw regulated by an endless chain and screw arrangement. The chain, as shown in the right of the engraving, passes over two toothed wheels, or, technically, spur-wheels. The latter are attached to the end of the two rods having square-cut threads eight to the inch. To each end of the parallel gauge is fastened a nut through which the long screws pass. Now, when this gauge is exactly parallel to the saw, any width required for ripping stuff may be quickly obtained by grasping the chain in the middle and pulling it one way or the other. Both screws will, under necessity, travel at the same rate of speed, as the chain can not slip. In obedience to the screw, both ends of the gauge will travel at the same rate, and the gauge will, in consequence, remain exactly parallel.

This is a great improvement over the old parallel gauge, for the following reasons: It permits of a very fine adjustment, even to the "splitting of a hair." If the stuff ripped is discovered to be a little "scant" or a little "flush," a slight pulling or pushing of the chain will secure the exact width. This could not be easily done by the old plan. Secondly, the gauge is held much more securely, there being no possibility of a shuck. Thirdly, when the required width for ripping is secured, the gauge does not have to be fastened down, the nut-and-screw arrangement holding it perfectly stationary.

Fourthly, should the saw get out of line, as it is apt to do, the set-screw holding one of the spur-wheels to the long screw may be loosened. By a slight turning of the screw, independently of the other, the gauge may be made exactly parallel to the saw. The set-screw, before mentioned, may then be tightened. We can furnish this machine, when desired, at the old price; *i. e.*, \$25.00, including the miter-board shown on top of the machine, and one of our heavy mandrels. Formerly we have sent out one of the small mandrels in one of these machines. For 50c extra we will put in a mandrel that will take 9 groovers.

WARNER'S AUTOMATIC MACHINE FOR CUTTING INSETS IN THE SECTIONS.

The next to which we invite your attention is an automatic machine for cutting the insets to the bolts, or pieces of planks, prior to being ripped up into strips. The bolts are simply piled in the tray shown in the rear of the machine. They are then automatically shoved through and thrown upon the floor in the foreground. This is done by a pair of endless chains with now and then a raised link so as to catch the blocks. The pile of blocks then drops down, and the bottom one is shoved out as before. The chain, together with a pair of raised links, is shown in the front of the machine. The device for holding the blocks firmly over the cutter-head as the blocks pass over is a series of four wheels mounted on two one-inch shafts. They are shown in the cut together with a pair of cutter-heads.

This machine will accomplish in three or four hours what would require a whole day by the old way of shoving blocks over a cutter-head by hand, cutting out but one inset at a time. Not only that, but it is operated with entire safety to the one feeding it.

Right here it is proper to remark, that this machine was the outgrowth of an accident to one of our old trusty men while cutting out the insets in the old way. A little knot was the cause, it having caught in the cutter-head, revolving at a high rate of speed.

The bolt was thrown suddenly out from under his hand, allowing it to fall upon the cruel knives. To prevent a repetition of such a thing we told our foreman, Mr. Warner, and our machinists, that we wanted them to get up an automatic machine which would preclude the possibility of an accident, and the foregoing is the machine.

We can furnish this machine, when desired, put up complete, for \$75.00.

P. S.—By way of caution, we wish to suggest to all of you who have to do with saws or cutter-heads, be careful; saws are treacherous things, rather more partial to the inexperienced. You will not appreciate the importance of being careful until you have mutilated your fingers. Several of our men have been hurt recently, and we speak whereof we know.

Shall not the Judge of all the earth do right?—GEN. 18: 25.

CONTRIBUTIONS FOR GLEANINGS.

I BELIEVE there has never been a time before when so many good articles were waiting for a place. As the winter is now about past, let us drop long essays, and get into practical work. Bright practical thoughts, expressed in few words, seem to be the demand now in journalism.

A BEE OR A COW—WHICH?

We clip the following from the *Rural Canadian*:

None but those who have studied the subject have any idea of the enormous waste of honey that goes on from want of properly qualified insects to collect it. Here, for instance, is a striking fact:—Given two fields of clover of equal size, side by side, one of which you pasture with cows and the other of which you pasture with bees, the one pastured by bees will produce a greater weight of honey than the field pastured by cows will of butter and cheese, and the cows will have eaten every blade of clover that is in the field."

The above statement may be true, but it seems a little astounding.

TERRY AND TOBACCO.

We are pleased to notice that the N. Y. *Tribune* of Feb. 9 has copied the greater portion of friend Terry's article from GLEANINGS, and also strongly indorses the position taken by your humble servant and others. May God be praised, that a paper having the moral weight of the *Tribune* has thrown its influence against tobacco.

THE POTATO-BOOK—AN APPENDIX.

By my request, friend Terry has written quite a lengthy appendix, giving all that is valuable that has come up since the book was written, two years ago. This appendix will be furnished free of charge to all who have purchased the book, by application on a postal card, and it will be included with the book to all future customers. We will furnish the 3 little hand-books—viz., Terry on the Potato, Terry

on the Winter Care of Horses and Cattle, and Prof. Cook's new book on maple-sugar making, for an even dollar, postpaid.

MR. THOMAS HORN.

As we go to press, Feb. 16, we have received letters from about fifty individuals who have sent Mr. Horn money. The greater part of the fifty have received no returns whatever. A few have had a part of the order filled. The amount claimed foots up to something like \$375. Mr. Horn fears it will be impossible for him to settle all claims *this season*. It was an error of my own in so stating it in our editorial last month. As the notes he proposes giving are payable in two years, he expects to take them all up before they are due.

A HONEY-APIARY.

As soon as the weather shall permit, we propose to locate a honey-apiary a few miles from the home apiary, for the purpose of more carefully testing some of the new appliances for producing comb and extracted honey. The large number of colonies in our own locality during past seasons has made it almost impossible to test some of the new systems of honey-production with any degree of satisfaction—the nectar of our locality being divided among five or six hundred colonies. None of our stocks have been able to secure more than enough to fill the brood-chamber, to say nothing about going above. Should foul brood reappear in the home apiary again this season, since the prices have been reduced it may be necessary to establish still another out-apiary. In any event our friends may rest assured that all who send for queens and bees will receive nothing but perfectly healthy stock.

OUR AGRICULTURAL PERIODICALS, AND DO THEY PAY?

OUR esteemed friend "Sam," in the *Ohio Farmer* for Feb. 12, makes the following point, which was gathered during the institute work during the past winter in Wisconsin: There is one township in that State where not an agricultural paper is taken, and the average price of butter for the year was 10½ cents. In another township, 214 agricultural papers are taken, costing about \$250, and their butter sold at an average of 23½ cts., the same year. As the amount sold in each township was not greatly different, it shows that, by paying \$250 for intelligence, they received for it the dividend of \$8100 over the township that takes no papers. In other words, the farmers who saved \$2.50 by not taking farm papers actually paid \$8100 by being too smart to take such papers. Besides the matter of butter, how much benefit did the others receive in other crops? And besides the crops, regarded from a dollars-and-cents view, what has been the effect of those 214 periodicals on the boys and girls? Still further, our agricultural press, as a whole, is striking heavy blows for righteousness and godliness (excepting a few of them on the tobacco question, but it is only a very few). The time is mostly gone by when it was fashionable to sneer at "book farming." I hope the agricultural press will pass this item around; and if it shall happen to fit townships in other States as well as Wisconsin, let us have it widely copied.

CONVENTION NOTICES.

The Pan-Handle Bee-Keepers' Association will hold its next meeting at Wheeling, W. Va., No. 1138 Main St., in K. of P. Hall, March 3 and 4, 1887.
W. L. KINSEY, Sec.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

THE T SUPER—ITS USES AND CONSTRUCTION.

FEVER since the first appearance of that practical little work by Dr. Miller, "A Year Among the Bees," we* have been discussing here in our establishment the merits and demerits, if any, of the T super. We have made several models upon a plan different from Miller's; but after carefully considering all the pros and cons of the various plans we have at last gone back to very nearly the original one as described in the doctor's book. The slight change was made with a view to simplify the construction of the T super as well as to secure one or two additional advantages, as it seemed to us.

The one figured below does not represent exactly the one which we propose to bring before the public, as we made a little change in it after we put it into the hands of the engravers. However, it will serve our purpose to illustrate the principle of the T super.

THE T SUPER.

The T tins, from which the super derives its name, is shown in Figs. 1 and 2, the latter a cross-section. Friend Miller, in his book, says it would be desirable if the T tins could be made of one strip of tin, but that his tinner informed him that, with ordinary tools, this could not be done. His tins were accordingly made by placing two tins, bent at right angles, together, as in Fig. 3. They were then soldered. These are just as good when finished, but are rather expensive to make. We now have a machine which makes the T tins of one strip of tin, as seen in Figs. 1 and 2.

We next were undecided as to whether we should make these T tins at fixed distances,

or whether we should make them movable, as in the Miller super. The engraving shows the tins as stationary. We had then decided to make them as in the cut, for the following reasons: First, the tins would always be in place, and, as a consequence, would not require to be spaced when putting in sections. Second, the T tins would not get lost.

After carefully reconsidering the matter we came to the conclusion that we ought not to deviate to any considerable extent from the plan given by so good an authority as Dr. Miller. We accordingly decided to make the super with the T tins movable, in spite of the fact that our engravers had illustrated the super as originally intended. The manner of construction which we have finally decided upon is as follows:

The two end-pieces of the shell of the super are $13\frac{1}{2} \times 4\frac{1}{2} \times \frac{1}{2}$; the two side-pieces are $18\frac{1}{2} \times 4\frac{1}{2} \times 5-16$. We next get out two strips of tin, $\frac{1}{2}$ inch wide, and in length equal to the inside length of the super; also

two strips of tin $\frac{1}{2}$ inch wide, in length equal to the inside width of the super. These strips of tin are bent at right angles along

their entire length. These are nailed along the inside bottom edge of the super, as in Fig. 4. A represents a section of the wooden side near the bottom edge, and B, C, the tin bent at right angles. Upon B rests the flat edge of the T tin, the edge C coming flush with the bottom of the wood.

ADVANTAGES IN HAVING THE SUPER MADE AS ABOVE.

Let us now consider one or two of the necessary advantages accruing from the use of movable T tins. They permit, first, not only the use of the $4\frac{1}{2} \times 4\frac{1}{2}$ section, but also the 6 to the L. frame, and the 4 to the L. frame. Where it is desirable to use either of the two latter, one or two of the T tins, as the case may be, may be dispensed with, and the others spaced so as to receive the sections. That is, this super will take a 1-lb., 1½-lb., and 2-lb., section, and, as we shall see, several widths of these sizes. Right here the reader will observe that the Moore crate, by reason of the partitions being at fixed distances, does not permit of the foregoing valuable function. Again, the T super, with movable tins, permits the removal of the sections *en masse*, by means of a follower, in the easiest manner possible. It is true, the Moore crate possesses this feature to a certain extent, but it does not seem to me that the sections can be removed as easily. Those partitions present a considerable amount of surface to the sections; and this, together with the added amount of bee-glue, makes a consequent increase of friction in removing the sections.

There is another very important advantage which the T super has over the Moore crate; namely, the former may be used either with or without separators, while the latter can not be so used. Last of all, the T super costs less.

The foregoing are the differences between the two surplus arrangements. In other respects they possess about the same func-

*"We" means Mr. Warner (our foreman), Mr. Calvert, A. I. R., when he is not off in the lots, and your humble servant. We're the "bosses," you know.

FIG. 3.

tions. One is, that they will take other widths than the 1 15-16—an advantage which can not be said of the combined shipping and honey crate. By the application of a little arithmetic we find that the T super and the Moore crate will take the following-named widths: 1 15-16, 1 11-16, 1½, and 1¾ scant, and the number of these required to fill a crate is, respectively, 28, 32, 36, and 40. These sizes are figured without the use of separators; but our foreman says that all of the above will shrink after leaving the saw, to permit the use of separators if desired. The sizes above do not include the 7-to-the-foot section, but the latter may be made to fit the super by piecing it out with another width of section.

The T super and Moore crate can both be tiered up; but the combined shipping and honey crate is not so constructed as to admit of this feature *inside the Simplicity hive*.

We can furnish the T super, made as described above, in the flat, including T tins and the L. tins, for 15c each; 10 for \$1.10, and 100 for \$10.00. T tins when desired separately will be 12c for 10, or \$1.00 per 100. If desired by mail, double above prices. L. tins, separately, 50c per 100.

SPECIAL NOTICES.

SOME IMPORTANT CHANGES IN THE 60TH EDITION OF OUR PRICE LIST NOW IN THE PRESS.

PRICES REDUCED.

YUCCA BRUSHES, TINNED WIRE AND SIMP. FEEDERS.

The wholesale prices on all these have been greatly reduced.

BEES BY THE POUND, NUCLEI, AND COLONIES.

We have reduced the prices of bees to where they were five or six years ago. Bees, \$1.00 per lb. in July, or 75c for ½ lb. Colonies, \$8.00 in July.

WIDE FRAMES.

Wide frames for 8, 6, or 4 1-lb. sections, will be \$2.00 per 100, or \$15.00 per 1000; 3 or 4 box cases, for the Doolittle surplus arrangement, \$1.50 per 100, or \$12.00 per 1000.

ALSIKE.

We have reduced the price of alsike to \$7.00 per bushel; \$3.60 per half-bushel; \$1.90 per peck; 15c per lb. Our seed is all clean and fresh, having been grown in 1886.

LAWN-MOWERS.

We sold so many of these last season, that, notwithstanding the advance in all iron goods, the manufacturers have given us better prices, and we reduce the price to you 50c on each machine. Prices will be, 10 in., \$5.00; 12 in., \$5.50; and 14 in., \$6.00.

COMB FOUNDATION.

We have made some new mills to run by steam-power, and are turning out better *fin* than ever before. We now offer four grades: Heavy brood, from 4 to 6 ft. per lb.; light brood, 7 or 8 ft. per lb.; thin, about 10 or 11 ft. per lb., and extra thin flat-bottom, about 13 or 14 ft. to the pound. Send for samples, and a new price list with revised prices.

BROOD FRAMES.

The price of our regular all-wood dovetailed brood-frames, including comb-guides, is reduced to \$1.20 per 100. The same, pierced for wire, without the comb-guides, same price; wire and tin bars included, 40c per 100 extra. Metal-cornered frames, \$1.00 per 100 more than all-wood. Frames with reversing devices and metal corners, \$2.30 per 100 more than all-wood; without the metal corners, 80c less.

PRICES ADVANCED.

It always gives us more pleasure to reduce prices than to advance them; but we are sometimes compelled to advance to get cost.

SCREWS, BESSEMER STEEL.

The price of wood-screws has advanced so much that we are compelled to withdraw prices in counter list, and advanced prices appear in next edition of price list.

WIRE NAILS.

We have revised the wholesale rate of wire nails, making a slight advance; but the retail price remains the same, except ¾ inch, which will be 18c per lb. instead of 17.

HONEY-TUMBLERS.

The manufacturers of glass honey-tumblers have advanced their price to us because of the general advance in glass goods; and as we sold these very close we are compelled to advance also.

GLASS.

Glass has been hard to get for some time, and prices have been advancing; and from the present outlook they are liable to advance still more. We hope it may not last long, and we have not marked up the prices of glass in our price list yet; but if there is any more advance we shall have to charge more than our list price; and if we do you will have this notice in advance.

SMITH'S FORCE-PUMP, OR SPRINKLER.

We have for some time been selling these pumps at wholesale lower than the manufacturer himself, though we did not know it, and it has caused him no little trouble in the way of complaints from his customers. He came to see us a few days ago, and we agreed to make our prices the same as his and other wholesale dealers'. This necessitates some advance in prices, and we hereby cancel all quotations and printed prices, and substitute the following:

Price of one pump, \$1.00; 2 for \$1.90, or 3 for \$2.75. A crate of 12 for \$9.00; a crate of 24 for \$16.00; a crate of 50 for \$30.00, or 100 for \$55.00.

Now, to compensate for this advance the pump has been greatly improved. The plunger is made differently, and these improvements make the pump cost more; hence the advance in price. There will be no deviation from these prices, except the cash discounts quoted from time to time. When ordered with other goods they will be shipped from here, and thus you will save freight by ordering of us.

ADDITIONS AND IMPROVEMENTS.

We have made quite a few additions and improvements which appear in the 60th edition of our price list, first among which is our

ONE-STORY CHAFF HIVES.

We have added to the price list a cut of this hive, with table of prices.

T SUPERS.

These are to be used to tier up inside the Simp. or chaff hive. They are illustrated and described elsewhere in this issue.

SAW-TABLE FOR HIVE-MAKING.

This is illustrated and described elsewhere in this issue. The table of prices of hives in the flat has been revised, and a new table of

HIVES IN FLAT, INCLUDING INSIDE FURNITURE.

Has been added. This we hope will be a help to many in making their orders, and in seeing at a glance the cost of different hives *complete* in the flat, without figuring it all out from different parts of the list.

Many other changes have been made too numerous to mention here, and that you may be posted you had better drop us a postal for a new list and samples of our comb foundation.

GOSPEL HYMNS.

We are now able to furnish Gospel Hymns consolidated, in paper covers, without music, for only 5 cts., and the little book contains all of the Gospel Hymns that have ever been published in numbers 1, 2, 3, 4. Sent by mail for 6 cts. These are especially intended for revival meetings, and will probably prove to be a great convenience. We can furnish 10 copies for 48 cts., or 100 copies for \$4.00.

We will give 20c for May, 1875, GLEANINGS, not 1885.

OUR catalogue of seeds for the greenhouse, garden, and farm is now ready, but it will be mailed only on application. It also contains prices of all kinds of vegetable plants—cabbage, cauliflower, tomato, pepper, kohlrabi, etc.

PROF. COOK'S BOOK ON MAPLE-SUGAR MAKING.

The book is now out, and is being mailed every day. If you have only a couple of dozen trees, I think it will enable you to save enough to pay the cost of the book. Price of the book, 35 cts.; postpaid, 38 cts.

GALVANIZED WIRE CLOTH FOR SEPARATORS.

We have just had an offer from the manufacturers, which enables us to furnish wire cloth, four meshes to the inch, No. 22 wire, for 5½ cts. per square foot. Where wanted in quantities less than a roll, the price will be 6 cts. per square foot; but at this price you must take it in pieces clear across the roll—that is, 3 feet wide. If cut to order, for separators, we shall have to make an extra charge for cutting, and whatever waste remains belongs to the purchaser. This wire cloth is the same size recommended by friend Betsinger, as nearly as I can recollect. You will notice, by a little figuring, that it costs considerably more than tin or wood. As to how much better it is than either tin or wood, experiment will have to determine.

WATERBURY WATCHES.

THE last series of Waterbury watches, which have been on the market nearly a year, are giving such surprisingly good satisfaction that it seems to me hardly right to omit mention of it. Every watch we send out is tested by the heads of the establishment; viz., I carry two every day, and John and Ernest each carries one. I rather think those I carry have the most severe test; for the young man who gives them to me, and takes them away again, sometimes has to chase out of doors after me to get them. Well, day after day the watches, when taken from my pocket, after having been carried 24 hours, are found to be right on the dot. One day one of the workmen found one in the mud where I dropped it, in jumping across the creek. Even that did not harm it.

A NEW EDITION OF GARDENING FOR PROFIT.

WHILE the above embodies all that the old book contained, it also includes every thing that Mr. Henderson has written for the agricultural papers since the old edition was out, besides bringing in all the improvements in the way of varieties in cultivation up to the present date. It also contains the latest discoveries and improvements in the matter of greenhouses; and it seems to me it is a book that any one interested in these industries can not well get along without. Peter Henderson is now one of the leading minds in market gardening in the world. It was my good fortune to have a visit with him a few days ago; and, although he is 63 years of age, he is as full of enthusiasm in every thing pertaining to vegetable and plant growth as he ever was in his life. Another thing that greatly pleased me was to see him so earnestly devoted, heart and soul, toward this problem of interesting the youth of the present age in honest, legitimate outdoor industries. The new book is so much enlarged, the price has been advanced to \$2.00, postpaid by mail. We can send it to you by express or freight, with other goods, for \$1.85.

PROFITS IN POULTRY.

THIS is the title of a new book, just received from the O. Judd Co., New York. As usual with their publications, it is well printed (250 pages) and profusely illustrated. As one mind can not well cover the whole range of experience and knowledge of an industry, O. Judd Co. have selected several of the best poultry-writers in the country to write the book, each writer upon his special branch of the industry, so that we have the cream of the various departments of the subject. Its whole tenor seems to discourage going too heavily into poultry at first. Its motto seems to be, "Economy all through." It tells how to make a coop for a small amount of money, just such a one as the average farmer feels he can afford. In its discussion of poultry-diseases it recommends only simple treatment—no expensive doses or tonics

which can be purchased of Mr. So and So. In short, the instructions all through are very simple, aided by different cuts. For instance, after one has read the chapter on "Caponizing," he is made to feel that he is already master of the art, so clear is the description. The book seems to be especially well adapted to the farmer and others who have no desire to spend their money in fancy blood, fancy coops, etc., but who wish to make poultry on a small scale pay. We have decided to put it in our book-list. Price by mail, \$1.00. If sent with other goods, by freight or express, 90 cts.

CIRCULARS RECEIVED.

The following price lists have been received at this office:

- An advertising sheet from Ezra Baer, Dixon, Ills.
- A 14-page circular of bee-supplies from Chas. H. Smith, Pittsfield, Mass.
- A 32-page circular of apianian supplies from E. T. Lewis & Co., Toledo, O.
- An 8-page circular of supplies in general from F. M. Atwood, Rileyville, Ill.
- A 4-page list of bee-keepers' supplies from E. C. Long, Williamsville, N. Y.
- A leaflet—"Facts About Honey," from Samuel Cushman, Pawtucket, R. I.
- A 12-page list of bee-supplies from J. W. Bittenbender, Knoxville, Iowa.
- An 8-page list of bees, queens, and poultry, from Jno. A. Thornton, Lima, Ill.
- A 4-page sheet of bees, potatoes, etc., from Ernst S. Hildebrand, Ashippun, Wis.
- A 12-page list of bees, queens, and supplies, from Jas. M. Hyne, Stewartsville, Ind.
- An 8-page circular of bee-keepers' supplies, from A. D. D. Wood, River Junction, Mich.
- An advertising sheet of quibby smokers and bee-hives, from W. E. Clark, Oriskany, N. Y.
- An 8-page (large size) circular of bee-keepers' supplies and poultry, from C. M. Dixon, Parrish, Ill.
- A 32-page list of fruit-boxes, bee-supplies, etc., from The Berlin Fruit-Box Co., Berlin Heights, O.
- An 8-page price list (large size), of poultry and bee-keepers' supplies from A. H. Duff, Creighton, O.
- A 14-page list of bees and queens, garden seeds, small fruits, etc., from Christian Weckesser, Marshallville, Ohio.
- An 18-page list of bee-supplies. Specialty: the Richardson hive and fixtures, from M. Richardson & Son, Port Colborne, Ont.
- A 4-page circular of supplies from J. H. Martin, Hartford, N. Y. Among the special features of this we notice his chromo cards.
- An advertising sheet—specialty, the Eaton section-case, from Frank A. Eaton, Bluffton, O. He also sends a 4-page circular of bees, queens, and poultry.
- A 32-page list of bee-supplies from E. Kretschmer, Coburg, Iowa. The circular also contains considerable information upon hives made invertible, sectional, etc.
- A 36-page catalogue of bees, hives, fixtures, and general supplies, from Edward R. Newcomb, Pleasant Valley, N. Y. The appearance of this tastily gotten-up catalogue is neat and novel.
- A 32-page list of supplies—specialty, bee-hives and crates, from G. B. Lewis & Co., Watertown, Wis. They put out this season new and desirable styles of hives, such as the present season will demand.
- A 12-page list (large size) of apianian supplies—specialty, chaff and Simplicity hives, from A. F. Stauffer, Sterling, Ills. We notice in the above, that Mrs. A. F. Stauffer advertises eggs from that much-prized breed, Plymouth Rocks.
- A 32-page circular of apianian supplies, Bee-keeper's Guide and Memorandum, from Jos. Nysewander, Des Moines, Iowa. Mr. N. was one of our former stenographers and clerks in the office of the Home of the Honey-Bees. We are glad to note his evident success.
- A large-size 50-page circular of every thing pertaining to the apiary, from Abbott Bros., Southall, London, England. These gentlemen are probably the largest apianian-supply dealers in England. They illustrate numerous styles of hives, quite varied in design—crates, honey-bottles, etc.

The following were printed at this office:

- A leaflet of apianian supplies for L. Purdy, Killbuck, Ohio.
- An 18-page circular of general bee-supplies, bees, queens, etc., for John Nebel & Son, High Hill, Mo.
- A 12-page list of apianian implements, comprising quite a complete list, for M. H. Hunt, Bell Branch, Mich.
- An 8-page list of supplies—specialty, Foster's Adjustable honey-case and hives for Oliver Foster, Mt. Vernon, Ia.
- An 8-page circular of bee-keepers' supplies for E. C. Kepner, Dunlap, Tenn. Mr. K. proposes to take students in apiculture. Write him for terms.

ESTABLISHED 1855. BEESWAX HEADQUARTERS.

We have constantly on hand a large stock of Domestic and Imported Beeswax in original shape, which we offer to manufacturers of Comb Foundation at lowest prices. We guarantee all our beeswax absolutely pure. Write to us for prices. Address

HONEY COLUMN.

CITY MARKETS.

ST. LOUIS.—*Honey*.—Honey still drags; the demand is very light; and to effect sales we have to shade prices.

White-clover, 1-lb. sections, 11@12
Wild-flower, 1-lb. section, 10@10½
Broken comb, 7@9
Extracted, white-clover, tin cans, 5@5½
White-sage and wild-flower, cans, 4@5
White, in bbls., Southern, 3@4¼
Beeswax, choice yellow, 25; medium lots, 22@23;
dark, 20, W. B. WESTCOTT & Co.,
Feb. 21, 1887. 108 and 110 Market St.

BOSTON.—*Honey*.—No change in prices, and demand is for one-pound sections of fancy white honey.

Feb. 21, 1887. 57 Chatham St., Boston, Mass.

CHICAGO.—*Honey*.—Sales small and not frequent. Commission houses are being urged to sell out consignments sent them some time ago; and as these are offered at buyers' figures, the market may be called weak. Extracted, very little being sold.

Beeswax, 25, R. A. BURNETT,
Feb. 24, 1887. 161 So. Water St., Chicago, Ill.

DETROIT.—*Honey*.—Very few sales reported, with large supply on hand, and prices some lower. Best white, 11@12c. *Beeswax*, 23c.

Feb. 21, 1887. M. H. HUNT,
Bell Branch, Mich.

CINCINNATI.—*Honey*.—We quote extracted honey at 4@7c on arrival. Choice comb honey, at 12@15c in a jobbing way. Demand slow.

Beeswax.—There is a good demand for this, which brings 20@23c on arrival for good to choice yellow.

Feb. 23, 1887. CHAS. F. MUTH & SON,
Cincinnati, Ohio.

KANSAS CITY.—*Honey*.—There is no change to report since our last to you.

Feb. 21, 1887. CLEMONS, CLOON & Co.,
Cor. Fourth and Walnut Sts., Kansas City, Mo.

CLEVELAND.—*Honey*.—There is no material change in honey. Demand continues very light with values unchanged. Best white in 1-lb. sections sell, at 13c; 2-lbs., 11@12. Dark 1-lb., 10c. Extracted, 6c.

Beeswax, 25c, A. C. KENDEL,
Feb. 19, 1887. 115 Ontario St., Cleveland, O.

MILWAUKEE.—*Honey*.—The demand for honey is very fair, and supply ample. We will quote white 1-lb. sections, 11@12; white 2-lb. sections, 10@11; Dark not wanted. Extracted white, in bbls., and kegs, 6@6½; in small quantities, 6½@7¼. Dark, in bbls. and casks, 3@5. *Beeswax*, nominal, 25c.

Feb. 23, 1887. A. V. BISHOP,
142 W. Water Street.

PHILADELPHIA.—*Honey*.—Honey continues dull at the decline noted. White-clover, fancy 1-lb. glass sections, 10c; same, fair to good in glass sections, and 2-lb. fair to fancy, 7@9.

Buckwheat, 6@8c, as to condition.
Strained, 5@6.
Beeswax sells on arrival. Choice white, 27@28; choice yellow, 23@24; dark, 20@22.

Feb. 14, 1887. PANCOAST & GRIFFITHS,
242 South Front St., Philadelphia, Pa.

COLUMBUS.—*Honey*.—No material change in market. White-clover in 1-lb. sections, 15@16c. Extracted, 10@12½. California honey, slow sale at 8@10c.

Beeswax, fair demand, selected yellow, 22@25c; dark, 18@20.

Feb. 21, 1887. EARLE CLICKINGER,
117 S. 4th St., Columbus, Ohio.

FOR SALE.—600 lbs. of very nice light-colored buckwheat honey, in kegs of 160 lbs. each, 5c per lb.

CHAS. T. GEROLD,
East Smithfield, Bradford Co., Pa.

FOR SALE.—I have about 300 lbs. of fall honey and honey-dew mixed, which I will sell to the highest bidder.

F. W. STEVENS,
Moore's Hill, Dearborn Co., Ind.

FOR SALE.—Six 48-gallon bbls. of choice white-clover honey at 6c per lb., and eight 10-gallon kegs at 6½c; 4 bbls. fine Spanish needle at 5c, and three 25-gallon kegs of fine mixed honey (Spanish needle and heart's-ease) at 5½c per lb. here on board of cars. Send 2-cent stamp for each sample.

EMIL J. BAXTER, Nauvoo, Hancock Co., Ill.

QUEENS. 1887. BEES. QUEENS.

MY ITALIAN BEES AND QUEENS can not be excelled in **BEAUTY** and **WORKING QUALITIES**. I make a specialty of **Rearing FINE BEES AND QUEENS**. Prices **Reduced for 1887**. Be sure to send for my NEW Catalogue before buying. Address
56d FRANK A. EATON, Bluffton, O.

"ENGLISH YOU KNOW."

How the genuine Bingham bee-smoker is looked upon in England, where we have no patents, and any one can make or use or sell just such smokers as he pleases or thinks best. The editor of the weekly *British Bee Journal*, Thos. W. Cowan, after using five full columns and nine good cuts in illustrating the Bingham bee-smoker (space and cuts that would have cost us more than one hundred dollars), says, "A real Bingham will send a greater volume of smoke, and that to a greater distance, than any other smoker we know. We have had such a smoker in use since 1878; and although we have been obliged to renew the barrel, which became worn through from constant use, nothing has been done to the bellows, which is just as good as it was on the first day we had it. A smoker like this will burn almost any sort of fuel that will produce smoke when smouldering. We use old rags, brown paper, or sacking; but peat, decayed wood, or even ordinary firewood, will do when it is well kindled."

For the lowest and the highest priced smokers sold in the United States, and the genuine Bingham & Hetherington uncapping-knives, send card for circulars to **Bingham & Hetherington**,
5tfdb Abronia, Mich.

PLANTS. Send a postal card and get my prices of all of the leading varieties of **STRAWBERRIES, BLACKBERRIES, CURRANTS, and GRAPES**. Prices very low. All stock warranted.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canada. To all other countries of the Universal Postal Union, 15 cts. per year extra. To all countries not of the U. P. U., 42 cts. per year extra.

DEVELOPMENT OF YOUNG BEES.

SOMETHING FURTHER FROM FRIEND DOOLITTLE.

LATELY I saw the statement that "bees seem to possess the power to retard the development of both eggs and larvae, as also to hasten this process," which may be true or it may not be true. That the development of young bees is greatly retarded at times and accelerated at others, no close observer will deny; but the question in doubt is, whether the bees have the power of thus hastening or retarding the development, or is it a condition or state of things over which they have no control? I believe, as has been lately given in *GLEANINGS*, that the egg is changed into larva only as it is touched by the pabulum from the nurse-bees, and thus far consider that the bees have perfect control over the hatching of the eggs; but further than this I think that the time of year, temperature, etc., have more to do with the matter than the bees. Extreme heat will so hasten development that I have known perfect young bees to hatch in less than 19 days, while very cool weather so retards development that several cases of worker-bees being in the cell for 24 days have come under my notice. In this connection I wish to give some experiments which rather go against my own conclusions, and favor the statement at the commencement of this article; yet as this retarding of development, which is to be spoken of, happened only at the closing of the season, I am not sure that such as comes in mid season is produced in the same way.

For two springs past I have experimented to find out the true temperature required for brood-rearing, by placing a self-registering thermometer inside the cluster of brood and bees. It is no hard

matter to get the highest temperature ever reached in a hive; but to get the lowest is quite another thing. As the outside air is always colder than that in the hive, unless in rare instances, all there is to be done to get the highest degree of heat is simply to place the thermometer in the hive, leaving it there as long as you wish when it is taken out, and the degree noted.

Before going further I will here state that 98° is the warmest I have ever found it to be in the hive in our hottest summer weather, when the mercury was but a very few degrees colder in the shade outside. How the bees can so keep down the temperature of the hive by ventilation is more than I can see; for a hive with no bees in it becomes so hot that animal life can not exist, as I once found by confining a hen for a few hours in a box about the size of a hive, which sat on the ground in the hot sun; for when I went to get her she was dead and nearly roasted. Do we know that the bees do so keep down the temperature by ventilation? May they not have some other means of doing it? But, to return: To get the lowest degree ever fallen to, we have to place the thermometer in a very warm place, so as to make it go up to 110° or over, when the steel registering-bar on the cold side is drawn down to this degree. If we now start for the hive with it, the cool outside air will cause the mercury to sink, so that our object is thwarted; and after a little thought I overcame this trouble in this way: I heated a piece of iron to 140°, and placed it in a box. A cloth was laid on the iron, and another over this, when the box was closed for a few minutes, so as to warm the cloth. The thermometer was now slipped between the cloth, and carried to the hive so that no cooling-off of any amount occurred, while the frames were being put in place to receive

it. In this way I was able to get the lowest point reached during cool nights, on some of which there was nearly a frost. This proved to be at the lowest 92° in all colonies having four frames and upward of brood. In a small colony having brood in only three combs I found 90° registered after a very cool night. From this we see that there is only 8° variation inside the brood-nest during the height of brood-rearing, if my tests are any criterion to go by. During all of these tests so far mentioned, the bees were as active as we usually find them in June and July, so that the activity of the bees may have much to do with this matter.

Now for the last experiment, which was made the last of September. For several years I had noticed that queen-cells in a queen-nursery, used on the Alley plan, would not hatch regularly after Sept. 1, the time varying from the usual 16 days to 24, and sometimes more, while later they would not hatch at all, and I found much the same conditions existing with frames of worker brood. A single experiment gave a temperature at this time of year of only 81° as that now maintained inside the brood-nest. At this time all that activity manifested early in the season was gone, and the bees were sluggish and idle, which might account for the whole matter, were it not that brood-rearing is retarded during the season of activity. Reader, here is a subject for study and experiment; and this somewhat disconnected article is written with the hope that such an interest may be taken in this imperfectly understood matter that we may soon know all about this interesting part of our pursuit.

Borodino, N. Y.

G. M. DOOLITTLE.

Thanks for the facts furnished, friend D. Although temperature is a very necessary item in the matter, I am inclined to think, from the experiments I have tried, that it is by no means the *most* important element. In trying to get a small cluster of bees to rear brood, I failed entirely, even when I had the temperature exactly where you place it. The activity that comes, say when fruit-trees are in bloom, is, I am very sure, an important element. I think I can see how the bees may lower the temperature; in fact, I knew of this before, for I have seen bees right in the blazing sun, where the entrance was large enough, keep the interior of the hive comparatively cool; and my opinion at the time was, that it was done by the evaporation of the thin, newly gathered honey. Converting any liquid into vapor carries off the heat very rapidly, and advantage is taken of this fact in ice-machines, to be seen at our expositions. No doubt the bees knew all about it long before it was discovered by human beings.

A MORAL QUESTION.

ONE THAT COMES FROM A YOUNG SUPPLY-DEALER.

MR. ROOT:—I wish to ask your opinion about a little matter concerning sections. My trade in them is not very extensive. On account of the very low rate at which I can get poplar here, and with my facilities for making them in the winter time, I am sure I can furnish them, freight paid to any point in the Eastern and Middle States, at a lower price than

they are now offered. My inquiry is this: Would it be right for me to lay my plans to do so next winter, as being the "greatest good to the greatest number" (of bee-keepers), or should I join with my brother-manufacturers in not injuring their trade, which they may have worked hard to get?

I admit, this may be a rather funny question, but I am young in the ways of the world, and perhaps Dr. C. C. Miller might want another act of "special legislation" on the ground of "priority of trade."

H. P. LANGDON.

East Constable, N. Y., Feb. 18, 1887.

Friend L., I am exceedingly glad to have you ask such a question before going ahead. I do not mean that I am able to answer it, for I am not—I can simply suggest. If you can furnish sections as you say, and your motive is a right and proper one, I do not know why you should not sell them at whatever price you can honestly afford to. You should remember, however, that we are having failures in business almost constantly, because some one new to the work undertakes to sell things lower than he can afford; that is, he fails to take into account the necessary expenses incident to doing almost any kind of business. I hardly believe, however, that I would agree to pay freight to all parts of the country. Some manufacturers advertise that they will allow a rebate of from 25 to 50 cts. per 100 lbs., in order to equalize freights. It seems to me the safer way for you would be, however, to advertise at a moderate price; then after you have done business a while, and have carefully kept account of expenses, come down a little if you can do so safely. I think it is very neighborly and kind to talk over the matter with other supply-dealers or manufacturers of sections, and avoid ruinous competition as much as may be. I would also avoid getting into so-called "rings," to keep up prices, especially where they are managed so as to keep prices above what they ought to be. The greatest good to the greatest number of bee-keepers is a very safe rule, I think, always remembering to be just and fair in all your transactions.

IMPROVEMENTS IN BUCKWHEAT.

HENDERSON'S NEW JAPANESE BUCKWHEAT.

AS buckwheat is one of the few honey-plants that can be raised by bee-keepers with a great probability of paying expenses on the grain alone, without any mention of the honey, we are ready for any improvements that may be made in the grain; and even should the improvement be just a slight one, it will amount to quite a sum in the aggregate, for we can just as well plant the best as to plant the poorest. When it comes to the matter of seeds, even if the first expense should be four or five times the price of the common variety, we can in one year, or, at the most, two, have the improved seed as cheaply as the poorest. Over we give you a cut of a new buckwheat illustrated in Peter Henderson's catalogue. We shall test it at once, and shall be glad to have it tried extensively by bee-men.

As we know nothing whatever of the plant except what Henderson says, we copy his description from his catalogue.

As far as we know, and so far as careful inquiry goes among men likely to be posted on such subjects, this *Japanese Buckwheat* is not only entirely distinct from all other varieties, but has never before been seen in this country, except in the limited area that we will shortly refer to. A thimbleful of this buckwheat was sent by a Japanese gentleman to a friend residing in New Jersey in 1883. The most of the product of that thimbleful met with a calamity, but enough was saved to enable

tie over it, as, sown on the same day with the silver-hull, it ripened a week sooner, and yielded almost as much again. To show what a yielder it is, we may mention that *one grain* was planted in a garden, and from that was obtained *850 ripe kernels*. This variety can be planted as far north as New Hampshire.

I had a small quantity of the New Japanese Buckwheat from you last year, which I planted on 5th day of July, 1886, and from this I cut, and had, in good clean buckwheat, 1392 pounds, which ripened earlier, and has produced more than three times the yield of the silver-hull with the same culture.

MIDVALE, N. J., Nov. 12, 1886.

DAVID BEAM.

THE NEW JAPANESE BUCKWHEAT.

the grower to sow in 1885 half a bushel, and the result of that sowing was *forty bushels* of good seed. A glance at our illustration will show that the kernels are at least *twice* the size of those of any other variety, and of a shape peculiar and distinct from all others. The color of the kernels is also most distinct, being a rich dark shade of brown. The grower of this buckwheat finds that the straw is heavier; that it branches more, and does not need to be sown as thickly as the other kinds. The flower made from it is equal in quality to that of any other buckwheat, and, as the yields show, is enormously productive. The party from whom we bought the stock, distributed in 1886 ten bushels among farmers in his neighborhood, and, on the 1st of October, he wrote to us that all are enthusias-

The New Japanese Buckwheat ripened about one week sooner than the old-fashioned kind, and produced more than as much again to the same amount of sowing the past season. FOMPTON, N. J., Nov. 16, 1886.

LEMUEL VAN NESS.

We have purchased one bushel, and can furnish it to our readers in five-cent packages, as we do all other seeds. In larger quantities, 10 cts. for $\frac{1}{4}$ lb.; 35 cts. per lb., or \$2.00 per peck. If wanted by mail, add 5 cents for each $\frac{1}{4}$ lb., or 18 cents for a whole pound. If you want further particulars from those who have raised it, write to the parties whose testimonials appear above.

A CART FOR MOVING COMBS ABOUT THE APIARY.

AN INVENTION THAT COMES FROM AWAY DOWN IN CUBA.

FRIEND ROOT:—I send you a diagram of our comb-cart. The cart is designed for carrying combs to and from the honey-house while extracting. The box, or body, of the cart, is 41 inches long, inside measure, and of ordinary store combs it will hold just 30. The box is made the right depth for the comb you are using. The top edge of the side board is rabbeted, to receive the projecting end of the top bar of the frame, and a full comb of honey hangs in the cart as nicely as it did in the hive. The wheels are cast iron, 22 inches high, with a tire, or face, $2\frac{3}{4}$ inches. The body of the cart, when the handles are held up, is just 5 inches from the ground. The wheels are fastened to the side of the box by means of a flange; that is, screwed fast to the box by 7 screws. The flange is 7 inches across, and the axle upon which the wheel turns is cast fast to this flange. You will see by this arrangement we can let the box down near the ground, thus doing away with the use of legs on either end, and still have the benefit of a pretty good-sized wheel. The wheels are placed in the middle of the box, so that, when it is loaded, there is little or no weight upon the hands; and the perfect ease with which we handle 30 full combs of honey with this cart would beat the oldest bee-man if he had never tried it. When we start out in the morning we have the cart full of empty combs, and the work of exchanging combs begins—exchanging empty combs for full ones. As fast as we take out a full one, we put in an empty one. We never open a hive more than once. Now, friend Root, this cart is my own get up, and it is not patented; and if you wish to make and use it you are free to do so.

A. W. OSBURN.

Havana, Cuba, W. L.

FRIEND OSBURN'S COMB-CART.

We are very much obliged indeed, friend O., for your very ingenious arrangement. The only trouble that I can see is, that the combs might swing while being wheeled, but I presume not more than they would on an ordinary wheelbarrow. Your idea of getting the shaft out of the way is an ingenious one, but I should think it would necessitate having the boxes made pretty strong; and with boxes so near the ground, it is rather necessary to have the apiary pretty well leveled and graded. I should think the cart might be extremely handy for other purposes, where the ground is even and level—say on the sidewalk, for instance. One could carry a great weight, and not feel it very much. Very light strong wheels are now made of steel, the same as are now used on our new wheelbarrow. Many thanks for your liberal offer.

A BOY'S SWARMING-BOX.

DESCRIBED BY THE BOY HIMSELF.

M. R. ROOT:—As I see swarming-boxes advertised in GLEANINGS, I thought I would send you a sample of my swarming-box. It beats the Kaler box, in my opinion.

There is no standing and holding a box up in the air for the bees to go in; no taking combs out of the box and putting them in the hive. Simply place your hives just where you want them, with your empty comb in the hive. Put your sections on, if you want them on. When the swarm commences to settle, hang the box over them. About nine times out of ten they will cluster in the box. If they are too long going in, take your smoker and smoke them a little on the under side. They will run into the box very quickly; then lift the box off the limb, carry them to your hive, pull out the pin at the top end of the handle, turn the handle to one side, dump the bees in front of the hive, and let them run in, and your work is done.

FELTON'S SWARMING-BOX.

Now, Mr. Root, please just take the little box and hang it on some of your shrubbery, and see how nicely it will hang. The handle will be supported by the limbs, so that it will hang almost anywhere. The little block on the side of the box, under the handle, is to keep from smashing bees. The notched piece on top of the box is for a handle. There is no better method for catching queens from after-swarms that I know of, than to catch them in this box and dump them on a sheet. Set the box back a couple of feet, and catch the queens while they are going to the box again.

My papa says it is the lazy man's swarming-box. When the bees commence to cluster, just hang the box over them, and sit down in the shade till they are in the box, in place of holding the box up in the air.

S. E. FELTON.

Newtown, Forest Co., Pa., Jan. 31, 1887

Very good, my young friend. No doubt your swarming-box will answer as you describe, but will not ours also? May be, however, yours is handier and easier to manage. If you have tried both, I presume very likely you are right about it. I am sorry you did not tell us how old you are. I think the engravers have made a pretty good picture of your device—don't you think so? I will explain to our readers, that a little model was sent in a paper box, with a letter, and the engravers made this cut from the model.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market.

ONE of our readers sends us the following, clipped from the *Detroit Free Press* of Jan. 28:

The artificial honey now made in New York is so close to the genuine that only the experts can detect the difference. It is in racks, the same as the natural product, and now and then the wings and legs of a few dead bees are to be found to further the deception. It can be sold at a profit for ten cents per pound, and the honey-bee may go.

On receipt of the same I inclosed it to the editor with the following letter:

EDITOR DETROIT FREE PRESS:—

Dear Sir:—Permit me, friends, to call your attention to the fact that you are doing great harm to a large class of people by the publication of items like the inclosed. We, as bee-keepers, have been following this matter up for more than two years, and I think you have been written to in regard to this matter, but perhaps you have forgotten about it. The statement is absolutely false in regard to comb honey, or honey in racks, as your item terms it. It is true, genuine comb honey of second quality has been sold as low as 10 cents per pound, but not one pound of manufactured comb honey has ever been brought forward in answer to the offer made in our journal, of \$1000, over a year ago. You can easily ascertain our responsibility; and to convince you that you are unquestionably mistaken, I will now pay \$1000 to be told where such spurious honey is manufactured. I think I should be safe in offering \$1000 for a single sample, were it not that something might be gotten up for the occasion, to make some sort of a semblance to artificial comb honey. We have been following the matter up for some time, and very many of our periodicals have publicly recalled, or contradicted, the false statements they have innocently made. The statements are greatly damaging the sale of real honey. Believing you are anxious to have truth and not error prevail, I have written you this letter. Will you not kindly return inclosed slip with your reply?

Yours truly, A. I. Root.

A prompt answer came to the above, as follows:

A. I. Root:—Such items get into print without any intention of doing any one an injury. A correction will appear to-morrow, and I will send you a copy of the paper.

C. B. LEWIS.

Detroit, Mich., Feb. 3, 1887.

And in due time the following from the pages of the *Press*:

It was mentioned in this column the other day that "artificial honey now made in New York was so close to the genuine that only experts can detect it." Letters from apiarists in Michigan and Ohio warmly deny the statement, saying the artificial can easily be detected, and that its manufacture and sale is a miserable fraud which should not be tolerated. We did not intend to either advertise or bolster up the fraud. Pure honey is cheap enough so that all can afford it, and the artificial would be dear at any price.

The above is somewhat of an apology for the erroneous statement, it is true; but I confess I felt saddened because we do not see a frank, free acknowledgment that the former notice was an error. Why can't the *Free Press* say there is no such thing made, neither in the city of New York nor in any other city? I am sure that neither

apiarists from Michigan nor Ohio stated that the artificial comb honey could be easily detected, for there is no such stuff, and never was. I have heard it stated from the pulpit, that the way to ruin is broad and easy because it is down hill; and our experience in this line seems to indicate that it is exceedingly easy for newspapers to catch on and push ahead in the line of telling lies; but it is terribly narrow, close, and up hill to tell the bare naked truth, especially when truth demands that the editor of a newspaper should fairly and squarely acknowledge he has been mistaken, or that he has unconsciously done anybody a wrong. May God help us to be bold and fearless in stating the truth when it comes our turn to apologize and retract.

THE TWO METHODS BY WHICH BEES PRODUCE SOUND.

AN INTERESTING ITEM FROM ONE OF OUR GERMAN COTEMPORARIES.

THROUGH the kindness of Mr. C. J. H. Gravenhorst we are enabled to present our readers with the beautiful engraving of the queen's respiratory apparatus as below. The remarks accompanying were taken from the *Illustrierte Bienenzeitung*, of Dec., 1886, of which Mr. Gravenhorst is the editor. The Germans are keen observers and close students; and we doubt not, that, as this question as to how the queen emits sound has recently been discussed, our readers will take pleasure in reading the following translation:

The *Bienenwater* contains a very fine article from the pen of the editor, in regard to the voice of queen-bees, which has greatly interested us. As is well known, the different views in regard to this

RESPIRATORY ORGANS OF QUEEN.

point do not agree one with another. According to Mr. Trell's theory, there is no doubt that bees, especially queens, have not only one voice, but also a second method of producing tones—the first by the movement of the wings, and the other by the respiratory organs. In the first case we speak of the tone given out in flight; in the latter, of a voice. The piping and teeting of the young queen is familiar to every apiarist. The first one is indistinct on account of the inclosing cell. The voice of a fertilized queen, like that of the drone and worker bees, is less noticeable. Bees do not breathe by means of a mouth and lungs, but through openings, or air-holes, called stigmata, of which there are two pairs on the under side of the thorax, and five pairs on the abdomen (see a, b, c, d, e, in the cut). Through these stigmata, the air enters through curiously made tubes, called tracheae, which, in the abdomen, expand into sacks of considerable size. In the midst of this breathing-

apparatus the voice of the bee is produced, similar to the way a tone is produced in whistling. The tracheae constitute the pipes, and the curtain-like film of chitin, which lies around the air-openings, represents the tongue. By means of the expelled air, the film is caused to give forth a tremulous tone. Now, the abdomen of a perfect queen is more strongly developed than is that of drones or workers; hence queens are able to give out a louder and stronger tone, piping and teeting; and even in a virgin state this tone is much stronger than when the body is distended by a full ovary and swollen oviduct, as shown at E and V in the cut. This is the reason why we hear weaker and less frequent tones from fertile queens.

with a disk or Acme harrow, or a two-horse cultivator, and drilling oats both ways, than to plow the ground. I have tried it by plowing every other narrow land, and I get the best meadow every time where the old sod is left down. If you wish to raise seed, you must save the first crop of peavine or alsike.

H. B. HARRINGTON.

Medina, O., Feb. 21, 1887.

OUR P. BENSON LETTER.

BEE-KEEPIN AS A OCKYOUNPASHEN.

HUMBUGS AND SWINDLES

WE notice by the *Western Rural*, that Mr. F. E. Fross, the man who gives away corn, is starting up again. This is what they say:

F. E. Fross.—F. E. Fross, of Ohio, sends to the *Rural* for its advertising rates. Our rates are a million dollars an inch to such people as you, Mr. Fross, and if that should not be high enough to keep you out of our columns, we should raise our rates. We have no use for you, your corn, or your methods.

That is the talk, good friends of the *Rural*, and we hope every paper will follow suit. We are willing to do almost every thing in the world to accommodate square men, but we have not space for a fraud, no matter how much money he has to pay for the space.

NEIGHBOR H. GIVES US A TALK ON CLOVER-SEED.

WHEN AND HOW TO SOW.

AS this is the time of year when every bee-keeper begins to inquire, "What shall I sow or plant for bee pasture?" I will try to give you a few pointers. I recommend clover.

It is the greatest honey-plant of America, and alsike stands at the head. We don't half appreciate it.

We should sow it everywhere—sow it on the roadside where the teams have cut up the sod, to keep out of the mud; sow it where the pigs have rooted up the sod in the orchard or pasture; give the boy a pocketful when he goes fishing, and tell him to scatter some wherever he sees a piece of bare ground on the creek-bank; put an under-drain in the cat-swamp, and sow some there; burn up all the brush-piles and old stumps, and sow alsike in the ashes. Remember that it makes the best pasture and hay of any plant that grows. Don't forget to mix a little white clover with it. They grow well together, and, at the price it is selling now, it is the cheapest grass-seed in the market.

PEAVINE CLOVER.

This, as a honey-crop, comes the last of July and the fore part of August, just the time when we need it most. It is the great crop to reclaim worn-out or poor land. There is no clay land too poor to raise a good crop of it. With 150 or 200 lbs. of good phosphate or bone-meal per acre, you are very sure of getting a good seed of clover after oats, on the poorest clay soil, and you will get oats enough at 25 cents per bushel to pay for your fertilizer, and get your clover-crop extra. If you have corn-stubble on last year's sod-ground you will get a better clover meadow by cultivating it

IT is no ockyounpashen in life more conducive to employment. Evry 1 in the land shoold keep bees from the 1,000,000 air a goin around with his gold-hedded cane to the tramp which brakes into Pringal's skewl hous evry nite to sleep. If evry man wooman & chiled hed a swarm of bees, what a soarce of happyness it would be. Besides these they ar sum uther classes which it is verry appropre8 to keep bees.

For instants, the farmer. Woarn out, fateeeged, weary and tired with the care and toil and fateeeg of hayin & harvestin, as he cums in all hot and played out, whot a releef it is to hev his mind diverted and his boddie refreshed by the soothin inflewents of hivin a swarm. Also the preacher.

BEE-KEEPIN AS A OCKYOUNPASHEN FOR THE FARMER AN HIS FAMLEY.

Now if ennybuddy in the world ot to keep bees its a preecher. Whot ennoblins thots arises in the expansiv vishens of the mind of l which contemplates the vass abiss of nacher in which floats dreemily backerds & forrerd8 a baskin in the solar light of the sun a 1,000 or may by a 1,000,000 tiny creechers stiled insex a floatin on thair gozzy wings, a dartin & a flyin, now here, now thair, a storin thair hunned sweets in thair waxen sells, which they will store more into l of mi noo hives than enny uther kind or variety. Under sitch inflewents they is a sightlent charm & the thots flows in his hed & brain, and wurd8 of silvery toned eloquents exhails in hunned axents of bammy mildness and limpid sweetness from his mellifloovus tung. * * * *

(Printer poot sum stars or suthin to make a poz logg enuff to talk in the buty of that air last.)

Then if the preecher gits boath ize stung shut, heel be blind to the faults of the peapel & look with a more leanyent i on thair failins, whitich sum peapel has a good menney. If he is stung into i i, when be goze into the poolpit a little girl will snicker, and that will help to keep people awake.

Also the invalid is espeshelly faverrable for the bizness. I think I have saw this stated befour. The invalid wants sum lite bizness & hede ot to keep bees for life. It's a verry lite bizness. The bees will lite all over him.

P. BENSON.

Apicultristical Bee-Keepin Sighentist.

NEW EXPERIMENTS

To Determine the Proportion of Honey Used by Bees in the Production of Wax.

THE PROPORTION OF HONEY CONSUMED TO MAKE A POUND OF WAX IS AN SIX OF THE FORMER TO ONE OF THE LATTER.

AS the discussion of foundation or no foundation, and economy in the production of wax, is now before our readers, our friend Dr. Miller has referred us to an article in one of our foreign exchanges, the *Bulletin d'Apiculture de la Suisse Romande*, written by that shrewd observer G. de Layens. Our proof-reader, W. P. Root, translates it as follows:

In the following experiments I was not altogether occupied with the idea of ascertaining whether bees build combs more or less mechanically with this or that kind of sugar; I simply tried to keep track of the quantity of honey the bees disposed of in working in the apiary, unrestricted, at a time when they chose to do that work.

The experiments made up to the present time differ so much one with another, that all methods are deceptive, and this is why it seemed to be interesting and profitable to recommence them on a different line of procedure.

Two questions, which have often been confounded in practice, and which should be carefully distinguished, present themselves at the outset.

First, when the honey-flow is heavy it is never advantageous to let the bees make wax, even when it costs but little to produce that wax; for, on the one hand, if one gives to the bees a few frames to build out, among a great number already built out, in order that, in building them, they may find sufficient room in the finished combs to store all the honey they gather, they will nearly always build drone combs. On the other hand, if one gives them frames only, to bring them to the condition of swarming, they will then build a large number of worker-cells; but not being able to place in these new frames for storage all the honey they gather, the prosecution of the work in wax will not go hand in hand with the harvest.

We see, then, that at the time of a heavy flow it is always preferable not to allow any work on wax to be done; but when, on the contrary, the flow is feeble, is it more or less advantageous to allow bees to work on wax? That is the sole question I shall try to answer.

The processes of experimenting, which, up to the present time, appear to be the best, are, in short, to choose two colonies, A and B, of equal size, of which the one, A, contains frames to be filled, and the other, B, the finished combs. After a certain time, the honey gathered by B is weighed, then that by A, then the quantity of wax produced; the difference between the weight of honey, compared with that of the wax produced, gives the proportion of the honey to the wax.

This method is subject to various errors.

1. When the queens are of exactly the same fecundity they do not lay, in the same number of days, exactly the same quantity of eggs, because, in one of the hives, there is, after the first day, all the room necessary to lay—room which does not exist in a colony that builds little by little. Then at the end of the experiments there will be more brood in the one than in the other, as the one uses different honey from the other—a difference which has not been taken into consideration.

2. It is generally believed, that if one selects, from an apiary, two colonies of the same strength, and of the same apparent activity, he can, without great error, compare the work of the two colonies; but it is often quite otherwise, as I am about to prove.

Having visited two colonies, Nos. 1 and 2, of which No. 1 was about twice as strong as No. 2, I increased the two colonies to the swarming condition. The bees thus becoming free to gather the crop according to their respective size, as they had no more brood in their hives, I weighed accurately the honey gathered by each of them at the close of a good day for honey. No. 1 had gathered 2 kilograms 140 grams* while No. 2 had gathered 2 k. 630—

*A kilogram may be reckoned as a little more than 2 lbs. 6 oz. A thousand grams make a kilogram.

that is to say, nearly as much, while it should have gathered at least a half less.

This year Mr. Bertrand proved to the contrary these same results. One colony gathered 37 k., while another, of about the same force, gathered, in about the same time, 18 k. The question here is not to explain these facts, but to prove that all experiments which depend upon a simple comparison of the work of two colonies of the same force, can inspire no confidence. Here are the circumstances under which I made my experiments:

1. The colonies worked freely in the apiary in the ordinary way, in order not to change the normal condition of their work.

2. The experiments were made at a time of year when the temperature was high—the highest at least 20 degrees Centigrade (70 Fahr.)—a temperature at which bees show a preference for a free state in order to make wax.

3. I selected, for my experiments, a time when the honey-flow was poor, in order to be sure that those colonies which built, as well as those that did not build, could find sufficient room in the combs to store all the honey they gathered.

4. I selected from the apiary two colonies of bees differing in the number of worker bees and brood, but which seemed, apparently, to work with the same energy. These two colonies, which I will designate by A for the stronger and B the weaker, were the only two which were brought up to the swarming condition.

A received 7 finished combs; then I inserted among these combs some frames for them to fill out. In this way I was sure to compel the bees to finish the combs, and that room should never be lacking for stores in the finished combs, in order that the queen might not be hindered in the least in her laying.

B received eight finished frames, so that the bees could not make wax in the wrong place.

5. I made two experiments in succession, each one lasting exactly eight days. At the end of the eighth day all the frames were taken away from the hives and replaced by others, but in a contrary way; that is, B then built combs, and A was kept from building. This method of increase was very important, for it permitted one, in working with any two colonies whatever, to obtain comparable results, summing up at the end of the experiments all their mutual differences.

6. At the end of these experiments, the honey gathered by A and B was added (these colonies made wax); at last the wax produced by the two colonies was added; but on account of great dampness the honey gathered during the 16 days of experimenting contained much water, so that at the end of the two periods none of the cells were yet sealed. The very thin liquid honey contained more water than sealed honey; and in order to eliminate this source of error I ascertained the density of the sealed honey and that of the honey which had been gathered. Afterward, in adding a sufficient quantity of water to the sealed honey, so as to give it the same density as that which was not sealed, I could easily find the quantity of water which the thin liquid honey contained in excess, which had been gathered, and subtracted this quantity of water from my calculations.

To sum up, the difference of honey gathered by the colonies which built cells, and those which did not build, indicated the weight of honey used to make a certain amount of wax.

7. During the 16 days of experimenting, the queens laid unequally, as they were of unequal fecundity; but it might have been that, during this period, the egg-laying did not go on constantly in the same proportion of inequality. That was, in effect, what took place. In the hives which did not build, the queens laid 16,064 eggs; in the hives which did build, the queens laid 16,634 eggs. This slight difference in brood represents the consumption of honey, of which the weight should be added to that gathered by the colonies which built; but as the eggs did not hatch till the close of three days, and as it was only at this moment that they commenced to use feed, only 358 larvae were fed, whose consumption of honey it is necessary to determine. According to the experiments of Berlepsch, the consumption of honey and pollen should have been 47 grams, to furnish sufficient feed till the 358 larvae should hatch out. According to other experiments which I made on this subject, I found that the bees used, to feed the larvae, nearly as much honey as pollen, of which 25 grams of honey was the maximum

amount used in order that the bees might feed a part of this brood, in which only a part of the cells were hatched.

To sum up: The difference in honey gathered was 1 k. 202 grams.

The wax produced was 191 grams.

The bees used 6.3 grams of honey to produce one gram of wax.

In the preceding experiments, the bees commenced to build combs in eight frames; and as the honey-flow was feeble, except the first day, they could build little else than worker-cells; I say little else, for in the corner of a large finished frame they built some drone-cells. These cells were built the first day, when the honey-flow was strongest (about 2 k. per day).

In practice, it happens that one can make worker comb for the bees economically enough by furnishing them honey at a low price. We find, for instance, that foreign honey in the Havre market can be had for from 50 to 60 francs per 100 k. (or \$9.37½ to \$10.25 per 250 lbs.); but to obtain these results, three conditions are necessary:

1. A light honey-flow.
2. Take away the frames of brood from a colony, and replace them by unfinished combs, inserting them between the full ones. These frames of brood should be given to feeble colonies.
3. Don't let them build, except at a high temperature.

We are exceedingly obliged to our friend across the water, for his suggestion of using two colonies, and then make them change about occasionally. A series of experiments conducted in this way must give us some pretty accurate facts. Perhaps we had better say, in our text-books, that, instead of 20 lbs. of honey to make one pound of wax, from 6 to 8 lbs. is enough. We are the more ready to accept this, as it seems to confirm the result of friend Hasty's experiments, given on page 642, 1886, and also friend Villon's, given at the National Convention at New Orleans.

MAKING BEESWAX.

RENDERING OUT WAX FROM OLD COMBS—FRIEND FRANCE'S METHOD.

I SUPPOSE that every bee-keeper makes more or less wax. If he doesn't, he surely is wasting material which could be made into wax, and so saved. I don't like to see any scraps of wax or bits of comb, or any thing that has beeswax in it, going to waste. Wax is worth money. There is always a cash market for all we can get. We keep at home a box into which we put every thing we have which will make wax—that is, scraps of comb, old discarded combs, or any thing we are going to melt up into wax. We always take with us, when we go to our yards away from home, a box holding nearly a bushel. Into this we put such things as scrapings of honey-boards, broken combs, drone combs, which we cut out, or any bits of comb. These we carry home, to be melted up. It is not then lying around, breeding moths. When it is made into wax there is a cash value in it, and it can be turned into cash at any time, or kept, if we choose to hold it for a higher price.

Now, after having saved up the material out of which to get the wax, how are we going to separate the wax from the refuse matter with which it is mixed, so as not to waste the wax, and at the same time not waste too much time? I suppose the supply-dealers would say, "Buy one of our wax-extractors." Now, it may be that they are the best thing in use for the purpose. I don't know. I never used one. But after I had seen them, and watched

other folks use them, I thought it was too putting a job. I have bought wax which had been worked out with them, and had wax sent me to work up into foundation, which was made with them. But generally there was more or less honey about the wax, and I was obliged to melt the wax in water to get rid of the honey.

Let me tell you how I have rendered out my wax. I have used the same plan, with slight changes, for about forty years; but I will say, that I never was satisfied with the plan. After I had become the owner of from 50 to 100 colonies of bees I took possession of the old rusty clothes-boiler, and purchased the wife a new one in its stead. I placed the old boiler over the fire in the kitchen, put in a large pailful of water, and then filled the boiler with such material as I had on hand, to be melted into wax. I have a good stout stick to stir it up when the water gets hot. The wax will melt and settle down. Put in more comb, and press it down into the water. Continue putting in and stirring, until the boiler is within two inches of being full; then stop putting in, but keep stirring until all is melted. Don't leave the boiler a moment now, for it is likely to boil over on the stove. Keep a dish of cold water within reach; for if it boils it will foam up and run over. If it can not be kept down by stirring, pour in a pint of cold water. As soon as it is all melted, take it off the fire and strain out the wax. For a strainer we have used cheese-cloth; but thin open cotton cloth was the best of any thing we ever tried. It is a yard wide. Take a piece a yard long for a strainer. Now we want a squeezer. Take two pieces of dressed inch lumber, about two feet long by five or six inches wide. Trim off the edges of the boards at one end, so as to make a good handle. Now lay them together, the wide ends one way. Fasten on a good stout leather hinge, to hold the wide ends together; let the leather run up well on the sides of the boards, and tack fast and our squeezer is ready. We next need a pan to strain into, and something into which to throw our rubbish.

We are now ready to strain. We want a dipper capable of holding about a quart or more, and one chair or box, for the one who does the squeezing, to sit on. It takes two persons to do this job—one to squeeze and one to twist the strainer. Now set the chair at one end of the boiler, just a little to one side; set the pan to catch the wax, close by the side of the boiler. Let the one who does the squeezing sit down in the chair. The other person takes the strainer, and stands at the other side of the pan, with two corners of the strainer in one hand and the 3d corner of the strainer in his other hand. The one sitting takes the fourth corner of the strainer in his left hand, and together they hold the strainer open over the pan. The one in the chair takes the dipper in his right hand, and dips out of the boiler into the strainer one or two quarts, then hands his corner of the strainer to the other person and picks up his squeezers, taking them by the two handles. He then opens them out, holding them over the pan. The other person then puts the strainer between the squeezers, and twists up the strainer while the other man, the one in the chair, squeezes. The strainer is turned two or three times, shaken down, squeezed, and twisted until the wax is out, and the rubbish is thrown out. The whole operation is again repeated until all that floats on the water is strained. Both pan and boiler are allowed to stand and cool, when there will be a thin cake of wax on the

water in the boiler, and a good cake of wax in the pan with some water under it. What comes out of the boiler will require melting over, as it is not strained.

Such a batch usually will make from 10 to 20 lbs. of wax; and for those who have but few bees, this plan is a very good one. The objections are, 1. It doesn't get all the wax out clean; 2. It bursts too many strainers, and they cost 5 cts. apiece; 3. It takes two persons too much time to do the straining.

I have studied over this wax business a great deal; for as our bees increased it was taking so much time. Finally, in the spring of 1886 I accidentally made a discovery which, for a large job at least, is very much more satisfactory. We had several sets of combs from which the bees deserted in the spring. After the hard freezing was over, the weather came on hot early, and those combs became wormy before we could use them. There was a large number of them, and the worms had got under such headway that it was not safe to put them in with the bees—not even the Italians. They therefore had to be melted up, and I could not get them through my boiler fast enough. We had a big iron kettle standing out there in the yard, that would hold about four bushels of potatoes to boil for the hogs. I got my eye on that kettle. A thought struck me (so hard that I nearly jumped out of my boots). "There is the wax-extractor that I have been looking for so long, standing there waiting to be used." I had three or four pails of water in it and a fire under it right speedily, and soon had it hot. Those worms quit eating beeswax. It is astonishing how much I could melt down in that kettle. I let the fire go down. So much wax rose on top (as the mass cooled off) that I dipped off, of clean wax, 25 lbs., and strained it at one squeeze. I then dipped out a large milk-pan full which I did not strain. As the wax in the pan cooled it sank in the center. I dipped out of the kettle all the wax I could, and then let it stand two days. At the expiration of that time I took a crust off the top of the kettle, about two inches thick, that took enough wax with it to hold it in chunks. Under the crust the rubbish did not contain a particle of wax. I threw the top crust into a box, cleaned out the kettle, then put back the cakes dipped off before, not strained. Besides these I put in a lot of trimmings from foundation, a nice lot of clean cappings, and some unfinished cakes from my boiler process. I melted them all up together, with three or four pails of water in the kettle. I then strained out two large dish-pans full of clean wax, one squeeze for each pan. I dipped the wax out pretty clean, then put in the rest of the wormy combs. The crust was first taken off the top of the kettle, of the other batch. When I got the second batch hot I dipped off all the wax I could, which was put in the first of the next batch.

With the big kettle we have worked out all our wax the past season. It is a big improvement. Its advantages are, 1. It takes much less time; 2. There is absolutely no waste. I get every particle of wax, and one strainer lasted all summer. Of course, when the bees would work on honey it would not do to work wax out of doors unless we wanted to cook the bees, for hot beeswax has a great attraction for bees, and they would fly into the wax in search of honey.

E. FRANCE.

Platteville, Grant Co., Wis., Feb. 1, 1887.

Friend F., a good deal of time was occupied at the Albany Convention in discussing

this matter of rendering wax, and I believe quite a few decided just as you have done, that a large iron kettle, hung up outdoors, is the very cheapest thing that can be used where the quantity of old combs is large. One of the brothers, whose name I can not now recall, spoke of putting all the combs in a coarse bag, and confining this bag under the water contained in the kettle, by means of a wire cloth. As soon as the whole apparatus gets hot, the principal part of the wax rises through the bag and meshes of wire cloth, to the surface, and may be dipped off. This makes the work automatic, as it were. It is perfectly strained, and is therefore fit for market as fast as it is taken from the surface of the water. When no more wax will arise, get out the bag while it is still hot, and press it with your squeezers, or some arrangement similar to a cheese or cider press. The size of the apparatus would depend on the amount of combs to be worked. You do not speak of the solar wax-extractor, and I presume you have not tried it; but why not, instead of pitching your waste fragments into a box, pitch them directly into the solar wax-extractor, and let old Sol get the wax out at his leisure?

EMPTY FRAMES VS. EMPTY COMBS.

SHALL WE USE OUR SURPLUS EMPTY COMBS, WHEN
HIVING NEW SWARMS, FOR COMB HONEY?

I FEEL quite certain that neither friend West nor friend Doane would wish to give a wrong impression; yet, from a lack of sufficient data, that is what has unintentionally been done upon page 93. In the first place I did not work 55 colonies for comb honey. It is true that I set aside that number in the spring with the intention of running them for comb honey, but, before any sections were filled, five of the colonies were broken up into queen-rearing nuclei; so friend Doane and I began the season with exactly the same number of colonies; *but*, his colonies were *stronger* than mine. His hives were ten-frame hives, while mine held only eight; hence he had in use 100 more combs—enough to have made 12½ more colonies like mine. If my opponents think this view unfair, let me ask if they would have considered it so had I changed my colonies over into ten-frame hives, thus making only 40 colonies of my 50? Right here, however, comes in another point, and that is, that some queens will put no more brood in a ten-frame than in an eight-frame hive (and that is why I use the latter), while many of them will; hence it would probably be unfair to assume that 50 ten-frame colonies are equal to 62½ eight-frame colonies; but I do insist that, in a comparison like this, it is unfair to assume that an eight-frame colony is the equal of a ten-frame one. Perhaps 50 ten-frame colonies would be equal, as honey-gatherers, to 57 eight-frame ones.

In regard to the *amount* of surplus, friend West is nearly correct. I had 300 lbs. more than he gave me credit for; viz., 7000 lbs. As he said nothing in regard to the shape in which the honey was secured, and as I raise comb honey, I presume the readers of GLEANINGS concluded that it was all of that class. Such is not the case; for 200 lbs. of mine was extracted, at the close of the season, from about 1000 unfinished sections, and the rest was in the shape of

finished sections; while, if my memory serves me right, about 1500 lbs. of the 6500 lbs. raised by friend Doane was extracted.

Yes, it is true that I had to feed my bees sugar syrup in the fall, but not so much as I wish I could have done. We had a good flow of honey, late in the fall, from the second crop of red clover, and the bees not only filled the brood-nests so full that but little feeding was needed, but stored considerable in the sections. Upon an average, about 5 lbs. of sugar per colony was fed.

I have no desire, however, to lead my readers to suppose that the non-use of full sheets of fdn. in the brood-nest, when hiving swarms, will lead to such brilliant results as the reading of this article to this point would indicate, as the question of increase is yet to be considered. My 50 colonies increased to 95, while friend Doane's went up to 125.

Let us reduce some of these things to their cash value. We will call empty combs worth 10 cts. each; sugar, $6\frac{1}{4}$ cts.; extracted honey, 6 cts.; comb honey, 12 cts. My comb-honey crop would sell for \$816. From this there should be deducted, for section boxes and fdn., about \$68.00, leaving \$748 for comb honey. To this add \$12.00 for the 200 lbs. of extracted honey, making the net result \$760. From this amount, however, there must be deducted \$29.69 for sugar, which leaves only \$736.31.

Friend Doane's 5000 lbs. of comb honey, at this same price, and with the same deductions for sections and fdn., would be worth \$550; to this add \$90.00 for the 1500 lbs. of extracted honey, making \$640; but from this must be deducted \$75.00 for empty combs used, which leaves, as a net result, \$565.

The question now resolves itself into this: Which is preferable at the end of the season—30 colonies of bees, or \$171.31 worth of honey? And let it not be forgotten, that, as already explained, eight-frame colonies are not ten-frame colonies.

And now, after having given this long explanation, I wish to say that I don't think it contains much proof either for or against the non-use of full sheets of fdn. in the brood-nest when hiving swarms. To be of any value, experiments of this class should be performed in the same apiary, with the same kind of hives, fixtures, and management, and the same strain of bees. I also wish to say, that the profitable production of honey does not depend upon large yields *per colony*, but upon securing it with the least expenditure of capital and labor.

W. Z. HUTCHINSON.

Rogersville, Genesee Co., Mich., Feb. 7, 1887.

It is true, friend H., that the report of Mr. Doane gives nothing very definite; but still it indicates, or seems to indicate, the advantage can not be so very great in the disposing of our surplus empty combs. Langstroth called empty combs the sheet-anchor in bee-keeping, and I believe he said they are better than money in the bank; and I confess I have been quite loth to give up this established axiom, as it were, in bee culture.—In regard to eight and ten frame hives, it seems to me that this matter depends much on what month the estimate is made. Very few colonies in our locality need more than eight frames before the middle of April or first of May; and if I were buying bees without regard to the hives that contained them, I would as soon have those in eight-frame hives as ten-

frame hives, say by the first of April. By the first of May I should expect a good deal of pollen; and some brood, perhaps, would be stored in the ninth and tenth combs. A ten-frame hive would be likely to contain more honey by the first of April than an eight-frame hive, and this honey should be worth something. So far as the amount of bees is concerned, however, I don't see that there will be ordinarily much difference. We rarely give any of our colonies more than seven combs to winter on. The space for the extra ones is occupied by the chaff division-boards until toward May.

DOOLITTLE'S QUEEN-CELL PROTECTOR AND INTRODUCING-CAGE.

A NEW AND CHEAP QUEEN-CAGE.

SOME time ago friend Doolittle sent us one of his queen-cell protectors. It was simply a square piece of wire cloth folded in the form of a cone, the sides overlapping. Into this Mr. D. had put a queen-cell from which the queen had hatched. The large end of the cone was stopped with a circular piece of wood. A small piece of tinned wire attached to the end served to suspend the wire-cloth cone containing the queen-cell between the combs. After considering the matter we decided that, with our facilities, there was a much nicer and better way to make the cone-shaped cages: that is, to stamp them out, so here they are.

Fig. 1.

Fig. 2.

QUEEN-CELL PROTECTOR.

Our readers would doubtless like to know how to make them. A wooden punch of hard wood is turned down to an inch and a fourth in size. One end of the punch is made conical, the cone being the same size and shape of Fig. 2. A two-inch hole is bored in a block of wood two inches thick. Next put the wooden punch, the cone end downward, exactly in the center of the two-inch hole in the block. Around this pour some melted lead or babbitt metal (preferably the latter), until the hole in the block is level full of metal. Allow this to cool, and

then draw out the wooden punch. Like a "duck's foot in the mud," the conical punch will fit the inverted cone exactly. Your tool is now ready for making the wire cones as in Fig. 2.

To make the cone, take a piece of wire cloth $3\frac{1}{4}$ inches square. Place this so that its center is just over the center of the hole in the babbitt metal. The punch is now put in the center of the wire cloth, and a couple of light strokes with a hammer drives the wire cloth into the shape seen in Fig. 2, with the exception of the small end, which is closed. With the point of a pencil, crowd the central mesh in the apex until of the size of the pencil.

You observe in Fig. 2, that the corners are spread out. The queen-cell is placed snugly in the cone. The corners are then drawn together, and a short piece of wire twists the ends together as in Fig. 1. The surplus wire should be long enough to hang down between the frames. When the queen hatches she has only to crawl out at the small end of the cone.

Bees have a mania, sometimes, for tearing down queen-cells, and I have sometimes found it a very difficult matter indeed to get the bees to accept cells at all. If I had had one of these queen-cell protectors, I think I should have succeeded.

There is another use to which this cage might be put; that is, introducing fertile queens. The idea came to us quite incidentally, and we feel pretty sure it will work, although never having tried it. The cage as in Fig. 1 would be the one we should use. Put the queen to be introduced into the end of the cage, and then stop it up with a small plug of Good candy. The cage is then to be suspended between the frames. In the process of time the candy will be eaten out by the bees, and the queen liberated. Our readers will observe that this principle of introducing is the same as in the Klimitz cage, which we have tried, and know will work.

We can furnish these cages with printed instructions, at the same price as given in GLEANINGS before; i. e., 3 cts. each; 15 cts. for 10, or \$1.00 per 100. If wanted by mail, add 3 cts. for 10, or 20 cts. per 100.

ERNEST.

MR. THOMAS HORN.

ALSO SOMETHING IN REGARD TO THE RESPONSIBILITY OF EDITORS.

IN response to our editorial of Feb. 1st, 62 persons have reported having sent Mr. Horn money, amounting to \$440.00, for which little or no return was ever made. Among the whole number, only two parties have claimed that I ought to pay back the money sent to Mr. Horn. The first one is as follows:

Mr. Root:—I wrote you last season regarding an unsatisfactory transaction with Thomas Horn. I received no satisfaction from Mr. Horn. I have postponed writing to you thus long, in accordance with your request in GLEANINGS. I have always been dealt with in a straightforward manner by yourself, and I desire to continue such dealing, if

this matter of Mr. Horn is adjusted satisfactorily. Now, in this matter I consider that any paper (this, too, is only the popular verdict) in which I see an advertisement, is the first party to a transaction, the advertisers the second; therefore with me I consider GLEANINGS responsible for ten dollars, sent to Thos. Horn last May, which, to date, has failed to put in an appearance, or value thereof. If you are willing to make the matter right—that is, the principal, I will charge no interest, and will take it out in goods and subscription to GLEANINGS, and in future shall compel them (if such parties get an order from me) to take the money from you, with your permission (myself first sending it to you).

I send you the letters received from Mr. Horn. I have sent you a great deal of money, first and last. You spoke in GLEANINGS of Mr. Horn's advertising the season previously. So he did. I looked it up. *Please do so yourself.* That advertisement was not the catch-penny affair of 1886. In 1885, Aug. and Sept., Mr. Horn says, "Look here." In May, 1886, "Horn pays express charges!" It blossoms out clear across GLEANINGS, "Pure Italians exclusively," and with "Stop! read and order!" This attracts orders to his pocket, and that, it seems, is the end of the order. Having lost bees quite heavily in the winter of 1885, I ordered, relying on your superior facilities for knowing what your advertisers' responsibility amounted to. If I am to lose this money, please take my name off your subscription list, and for numbers sent, Jan. 1st and 15th, I will pay for them. Please return Mr. Horn's letter, which I send as registered mail-matter.

GEO. T. REMINGTON.

Wilmington, Del., Jan. 24, 1887.

Friend R., if I pay you back the money you have lost, of course it is my duty to pay the other \$430.00 in the same way. Where an editor, by carelessness, or even by being deceived, permits a deliberate swindler to gain access to his columns, I can pretty nearly if not quite agree with you; but if we are to be responsible in all cases where losses come, how are we to know beforehand which one of the brethren is likely to fail in business, and which one is not? Our facilities for getting at the responsibility of our advertisers are certainly superior to those of our readers. You say Mr. Horn's advertisement, to the effect that he would pay express charges, etc., bears upon the face of it the appearance of a catch-penny affair. So it did seem; but nowadays, good substantial men often make pretty liberal offers to secure custom. We made careful inquiries in regard to Mr. Horn; and not only his postmaster, but the officers of the bank in the town where he resides, pronounced him all right. He had also been doing business for several months in a satisfactory way. Suppose we had declined the advertisement, would he not have declared at once, publicly and privately, that A. I. Root would not accept any advertisement that threatened to run against his own business, or that offered things at a lower rate than he did? You know what has been said about publishers and supply-dealers, in this line. Since we are discussing this matter, perhaps it would do no harm to speak quite plainly. When the *Bee-keeper's Magazine* came out with a flaming

advertisement, to the effect that they had come down to 25 cts. a year, and also that they would send both GLEANINGS and the *Magazine* for \$1.10 we felt somewhat anxious about the matter. If we refused to accept the advertisement, we were open to the charge of being afraid of our own pocket-books: if we received it, and the journal were published for only a few months, then we should be censured, just as you are censuring me now. Is it not true, that the only thing we can do is to act according to the best of our judgment and wisdom? In regard to the *Bee-keeper's Magazine*, I am happy to say that the editors are very nice young men; and, so far as we can tell, they are quite able to send out their journal several years, without getting more for it than the value of the paper upon which it is printed, if they choose to do so. I believe them to be honest and straightforward; but I wish to be distinctly understood that *I can not be in any way responsible for the success or failure of their new undertaking*. Under the circumstances I am sorry to bid adieu to an old customer, but I do not see how I can do otherwise, conscientiously, friend R. Here is the other letter:

Mr. Root:—I see by GLEANINGS that Mr. Horn has authorized you to collect all claims against him. He is in debt to me some, but I'd rather have the letter he wrote me than his note for two years. As he says we can add 10 per cent for the use of the money, which would be unlawful in New York, 6 per cent being the interest here, he could cheat us on the note, and with a good deal more honor, than he can as it is. Mr. Root, I want to show you how I got caught by him through you. I wrote you last spring, asking you if I could buy bees and queens by the pound, and turn them into the hives on my old combs (my bees having died the winter before), and make a success of it. Instead of answering my letter you sent me a postal card referring me to your A B C book, which vexed me at the time, I having heard you are a square man to deal with. I intended to buy the bees of you. I wanted ten pounds, bees and queens, so you see if you had answered direct, saying yes or no, I should not have been caught by Horn.

Perry, N. Y., Feb. 3, 1887. JAMES R. WRIGHT.

I confess that I was obliged to smile a little in reading the above, even though I am very, very sorry for our friend's losses. It looks to me something this way: He came to our store to trade, and found us so full of business that we had not time to treat him as courteously as we should have done, therefore he goes and trades at another store, and then blames me because he got into trouble. I am very sorry indeed that we are obliged to refer so many questioners to our price list and the A B C book; but so many times the clerks have given answers to inquiries that were not at all what I wished, that I have repeatedly directed them to refer such inquirers to the A B C book, where I have answered such questions carefully and deliberately. There have been so many inquiries every spring in regard to buying bees to put in hives left by the bees that have died, that I gave a page or two to the consideration of the matter, in the A B C book. The questions to be

answered are something like this: How many bees shall I purchase with the queen? Shall I buy them in April, May, or June? Is it necessary that they have a brood-comb? Will they make a full colony the first year? Shall I be likely to get any honey from them? Now, suppose I were to dictate to our shorthand writer this whole story to many different inquirers, each spring. Why, I would almost rather give them a book apiece than undertake to do it. I might have some leaflets printed, so as to cover the ground, to give away, and I believe I will have it done this very spring. I am very sorry indeed to appear disobliging, and I believe that those who have read GLEANINGS during these past years know that I do not mean to be; but, my friends, there is a limit to the mental and physical strength of even a big strong man, and I am neither the one nor the other.

HIVE-MAKING IN "THE HIEST STYLE."

FRIEND STOVER'S SUGGESTION.

FRIEND ROOT:—Being a mechanic, I have been considerably interested in the engraving on p. 278, A B C book. I also noticed your reply in GLEANINGS, to a query concerning the hexagonal bee-hive, saying the inventor tried to see what he could make. I herewith send you a drawing of a proposed chaff hive, or hives, to be of the standard size.

STOVER'S TENEMENT HIVE, ADAPTED TO THE LAWN OR FLOWER-GARDEN.

The spire is to be 6 ft. high, covered with tapered shingles $2\frac{1}{2}$ inches wide. The staff on the spire is to have a flag, not shown in the cut. It will have all the brackets that are shown in your catalogue. I expect to set it in my lawn along the street, in order to attract attention and make people "talk bees," which is the only advantage I claim for it. I have been employed by neighbors to make chaff hives; and the higher the bee-fever gets, the more hives I can sell. I purchased two colonies last summer, more for the purpose of studying the nature of bees, than for gain. I am getting to be very much interested since studying the subject. There is no telling where I shall stop. What do you think of the hive?

LEVI STOVER.

Brookville, Mont. Co., O., Feb., 1887.

I think, friend S., that it fills the bill pretty well, for all the advantages you claim for it, but you are very modest. Most of the patent-right bee-men would claim that

the bees would make more honey in it, is easier to operate, and ever so many other things besides its attractive appearance.

A PICTURE OF THE HOME OF ONE OF OUR A B C SCHOLARS.

THE PLACE WHERE FRIEND HEACOCK "GETS HAPPY."

WE have had so many pictures of apiaries that cost large amounts of money, and that were the result of years of labor, I had thought it might be a little refreshing, by way of variety, to have at least one glimpse of an apiary belonging to one of our boy bee-keepers—at least we call him a boy, for he is only 20 years old. Here is the picture, dear friends.

clear as it could be, and the thermometer stood at 66 degrees at noon in the shade. I write to you this way, because every thing I know about bees I got from you. I came here three years ago, and didn't know a bee from a yellow-jacket. So much for reading your A B C and GLEANINGS. I am an A B C scholar only 20 years old, and not very stout. I never took a chew of tobacco nor tasted whisky. Volusia, Fla., Dec. 29, 1886. O. E. HEACOCK.

Now, my young friend, I wonder if you know how much I like the ring of that last sentence of yours—"I never took a chew of tobacco nor tasted whisky." May God grant that you can say that to the end of your life! How I should like to take a half-holiday down in that Peach-tree apiary! I wonder if there is not a nice garden t'other side of that picket fence; and aren't there

PEACH-TREE APIARY, BELONGING TO ONE OF OUR BOY BEE-KEEPERS.

Friend H. does not write a very long letter, so all I can tell you about this bright little spot away down South is what we gather from the brief letter below.

WHAT AN A B C SCHOLAR SAYS ABOUT GLEANINGS AND THE A B C BOOK.

I thought you would like to see how an apiary looks in the far-off South, so I will send you a picture of mine. It was taken the 18th of Dec. While your bees in the North are housed up, ours are bringing in pollen. They have been carrying pollen and honey pretty fast for the last ten days. The peach-trees don't show very plain, for they were set out only last February; but they have grown very fast, as they are about ten feet high, and will bear peaches this next year. Christmas was the most beautiful day I ever saw. It was just as

some orange-trees somewhere in the neighborhood that bear rusty Florida oranges? Our friend Nellie Adams has just sent us two boxes of those rich, sweet, juicy Florida oranges. Why, it almost makes me well and strong just to think how I have enjoyed them. They got bruised considerably on the trip, and some of them were likely to spoil unless they were used up pretty soon, and I concluded I was just the chap to help keep them from spoiling; and when I took my tramps across the fields I used to have a big orange in each pocket and one in each hand. But, about the Peach-tree apiary: If friend H. were not present I would call attention to the fact of what a nice clean upright boy he is. He is rather tall, but he is honest and true. I do not know whether

the comb fell out of the frame he is looking at so intently, on account of the hot weather away down in Florida, or whether the engraver forgot to put it in. The small boy over there is probably his brother, and he, too, is having fun in the apiary. By the way, friends, did you know it is a grand thing to get small boys interested in bee-keeping? Perhaps it is a chunk of honey he is putting in his mouth, so as to prevent the honey from being wasted (the way I did with the Florida oranges, you know). Never mind the chunks of honey—they are better and cheaper than chunks of tobacco. The place is so pleasant that a couple of ladies have come out there to look it over. By the way, the best way to make any place in the world pleasant is to have the women-folks there. Friend H., why do you put your hives on stilts? Doesn't it bother the juvenile bees to climb up? I presume they never get chilled, however, in your sunshiny clime. Well, God bless you all, boys and girls; and if Uncle Amos goes down to Florida (which he hopes to do some time) he expects to visit the Peach-tree apiary.

MRS. COTTON'S SYSTEM OF FEEDING BEES.

EXPLAINED AND DEFENDED BY HERSELF.

I AM requested to define *clearly* my position as to feeding bees, through the columns of GLEANINGS, as there are many who mistake my position, and many who, either from a misunderstanding or from a desire to misrepresent, are constantly publishing statements calculated to mislead the public. My plan of feeding is intended to encourage the bees to breed rapidly in early spring, and to furnish the bees nearly all they require for their own consumption, that we may obtain, in glass boxes, in the best possible marketable form, nearly all they collect from natural sources.

If there were no honey obtainable from natural sources, it would not pay to feed bees; but it is plain to every intelligent person, that, in order to receive the greatest possible profit from bees, they must be fed. The only question is, how, when, and what to feed. It will pay as well to feed bees as to feed our domestic animals—cows, sheep, etc., or manure plants, or any crop the farmer cultivates, to stimulate growth and increase the product and consequent profit of the same. There are other points in my management of bees which are often misrepresented, but I have not the time or space to go over them in detail. Suffice it to say, I am ready to stand by my statements at all times; and in all my business transactions I intend to be guided by the golden rule; viz., Do by others as I wish others to do by me. MRS. L. E. COTTON.

West Gorham, Me., Feb. 14, 1887.

But, my good friend, you do not directly reply to that part of your chapter on feeding, where you state that, if sugar syrup is stored in the surplus-receptacles, no one can tell it from white-clover honey. Do you not think it would be well to change or modify this clause? The point you make, that a much larger yield of clover honey will be obtained by feeding the bees clear up to the comb-building point, is, without

question, a big item; but let us remember the charges that have been brought against us, of feeding sugar and glucose, and selling it as real honey.

HOW TO FEED BEES IN A CELLAR.

A FEW SERVICEABLE AND TIMELY HINTS FOR THE NOVICE.

TO those who have weak colonies in the cellar that need more bees or honey or both, I will say that they can be built up now just as well as when on their summer stands; and there will be no trouble about quarreling, or bees returning to the hive from which they are taken. Spread the combs of the weak colony, leaving a space in the center of the cluster of bees for one comb. Then go to any colony that has plenty of bees and honey, and get the outside comb *that has bees upon it*. You may look it over to see that the queen is not upon it, if you wish; but there is not one chance in fifty of the queen being on these outside combs, in the winter season. Place this comb of bees and honey in the center of the weak colony and they will cluster together, and all will be well. You may give them another comb in a day or two, if thought best, or two can be given at one time in the same manner. Many think that bees should not be disturbed in any manner when in the cellar; but there will no harm come to them by performing any needful operation with them in the cellar, as they will soon resume their former quiet after being disturbed. Bees will only occasionally take wing while being handled in the cellar, especially if the light is kept back and not allowed to shine directly upon them. But they have a disagreeable way of crawling about over the combs and upon the hands of the person working with them. It is better, of course, to build up or unite weak colonies in the fall, though many of us will neglect it then, and severe weather finds us with weak colonies, perhaps with valuable queens which we wish to winter over, while there are other colonies that were not "tinkered" with to introduce these queens, that have bees and honey to spare. And it is better to equalize them, as nearly as possible, in the cellar, than to leave these weak colonies to be strengthened after being placed on their summer stands. These little weak colonies, when fussed with in cool weather in April, are inclined to swarm out, and we see our little colony in the air with a valuable queen which perhaps we do not care to lose. They also have a provoking way of attempting to join some strong colony in a box hive, with crooked combs and "old black" queen, which we intended to transfer and Italianize in May, and, of course, are all slaughtered, leaving the novice with the empty combs and hives, to buy queens and try his hand at Italianizing again another year. L. C. CLARK.

Granada, Kan., Feb. 1, 1887.

Friend C., I know that bees can be fed in the way you mention, at times; and at other times (at least so it has seemed to me) the same directions do not seem to answer at all. The bees get on a stampede and fly all over the cellar, and do every thing they ought not to do. May be with some experience, however, I might manage better, for it was among my earlier experiences that I tried to feed bees in the cellar. I think,

also, there is more danger of getting the queen on your comb than you seem to recognize. Where the cellar is moderately warm, the queen will sometimes be found clear on the outside combs.

FUNCTION OF SALIVA.

PROF. COOK TALKS SCIENCE TO US SOMEWHAT.

IT will be remembered, that in my criticism of Mr. Cheshire's admirable book I said it was strange that he spoke of saliva as the digestive liquid of starch. Mr. C. also speaks of the lacteal system as the exclusive absorbent system, whereas it is well known that the portal system of blood-vessels absorbs nearly all of the digested food except the emulsified fats. I do not refer to this to condemn the book, for I think it a most valuable addition to our bee-literature—indeed, the most complete work ever written. No one person can know every thing; and to make a few errors, only shows the author to be human.

In GLEANINGS, p. 644, 1886, Mr. Cornell says I probably follow Dalton in denying that the "principal office" of saliva is to digest the starch. Now, Mr. Editor, I do not hold this opinion because Dalton does. I really believe nearly every physiologist now thinks the pancreatic juice the chief agent in changing starch into sugar, and that the principal function of saliva is mechanical. Huxley, in last Ed. Physiology, says: "The conversion of starch into sugar, which seems to be wholly or partially suspended in the stomach" (surely there was little time for change in the mouth) "is resumed, the pancreatic and intestinal juices operating powerfully in this direction." That saliva will change hydrated or cooked starch to sugar, no one doubts: that it does do it to any extent, I have not the least idea. Foster, our latest and best English authority, says, p. 242, that by the pancreatic juice the starch is changed into sugar; though most English authors, and Foster with the rest, argue that saliva may do a part of this work. Now for my reasons:

1. Saliva digests only cooked starch. Most animals do not have their starch cooked, and yet their salivary glands are as large as are ours, and they secrete as much saliva. All physiologists agree, that in dogs this is no part of the function of saliva, yet dogs secrete much saliva. Again, all physiologists know that the change which commences in the mouth stops in the stomach, and commences again only as the food comes in contact with the pancreatic juice. We all know how active the absorbent vessels of the stomach are. It is probable that the saliva is all absorbed in the stomach, and that little if any goes into the intestines where the starch is digested. Again, we all know how necessary saliva is in mastication. The great Barnard proved this by his grand experiments. Try to eat crackers when very thirsty. We can hardly do it. The blood lacks water, and the salivary glands can not secrete enough saliva to moisten the crackers. The old "rice ordeal" of India was a scientific test. The supposed criminal was asked to eat dry rice; if he could eat it quickly he was adjudged innocent; if not, guilty. It is well known, that anxiety stops secretion. The guilty man feared, knowing his guilt. His spittle was shut off, and he could not eat the rice. The

innocent man had a clear conscience; his glandular machinery worked well, and he could easily masticate and swallow the dry food.

But the most conclusive tests may be easily tried by Mr. Cornell or any other person. By macerating the salivary glands, stomach, and pancreas, separately, we can secure, by use of glycerine, the several ferments—ptyaline, of the saliva; pepsine, of the gastric juice, and the ferments of the pancreatic juice. Now, if we put the first in a test tube with cooked starch at 100° F., it commences quickly, but not very energetically, to change the starch to sugar. But as soon as we add the pepsine, the stomach ferment, acidulated by either hydro-chloric or lactic acid, this stops. Here we imitate nature exactly. But when we add the pancreatic juice to the starch it acts quickly and powerfully to transform it to sugar.

A. J. Cook.

VINEGAR FROM HONEY.

SOME VALUABLE FACTS FROM FRIEND MUTH.

FRIEND ROOT:—Having seen, in GLEANINGS, an article on honey vinegar, I shall express you a sample of ours; and if you ever saw a better article, let us know it, please. We have been making honey vinegar for the last four years, and find a ready sale for it. It eclipses the best vine vinegar for all purposes for which vinegar is used. Below I will give my modus operandi:

When making vinegar, one must know that water will turn into vinegar providing it contains the necessary quantity of sugar stuff, and is exposed to fresh air and a warm temperature. The warmer the temperature and the better the circulation of air, the sooner vinegar forms. A barrel is laid down, and an inch hole is bored in the upper end of each head, near the upper stave. This admits of a good air-passage over the body of the honey water. Tins with fine perforations nailed over these holes, with the rough side outward, exclude flies and skippers. Take about 1-lb. of honey to 1 gallon of water, thoroughly mixed up, and nail a perforated tin on the bung-hole. We take 35 to 40 lbs. of honey for a barrel containing 40 to 45 gallons of water. The warmest place in the yard is the best place for the barrel. If the sun shines on the barrel all day, it requires from the beginning of April to the end of October to make vinegar satisfactory for all purposes. If not sour enough by fall, it will be all right by Christmas or spring, if placed in the cellar or a warm room.

No vinegar should be exposed to frost before the sour fermentation is complete, as such would turn the sour into a foul fermentation, and the vinegar be lost. We made last summer, on our bee-roof, 10 bbls. of honey vinegar like the sample I send you. The retail price is 33½¢ per gallon, which gives us a better profit than the production of honey, as you will see.

CHAS. F. MUTH.

Cincinnati, Ohio, Feb. 5, 1887.

The samples of vinegar received are, to my notion, the finest I ever tasted. The honey flavor is quite perceptible, and is so pleasant to the taste I poured a tablespoonful in a glass of water and had a real refreshing tart summer drink. I do not know why it would not make a good substitute for lemonade. With such a price as you mention, friend

M., there is no trouble in making it pay; but in our market, 20 or 25 cts. seems to be about all anybody wants to pay for vinegar, even at retail.

BEE LEGISLATION.

THE CONCLUDING CHAPTER ON THE SUBJECT, AFTER WHICH FRIEND MILLER STEPS DOWN AND OUT.

NOW, Mrs. Harrison! I didn't think that of you. I thought that, instead of joining in with the crowd, your kindly nature would incline you to take up the side of the weak. Your article on page 53 speaks, like others, of priority of location, a thing which I have repeatedly said has no part in the question given to the committee of the N. A. B. K. society. You speak in your opening sentence of "such a covetous, selfish spirit manifested among bee-keepers as to favor legislation that would deprive any one, so disposed, of the pleasure of keeping bees. They must be looking," etc. Don't worry, my dear sister; there's no "they" in the case. There isn't a living soul among them, except myself, who has said he wanted any such legislation, and I am sure I shall never petition for legislation alone. Neither do I, the only covetous and selfish one in the whole lot, want any legislation that will deprive any one of the pleasure of keeping bees, any more than I would deprive them of the pleasure of farming. I would have the two callings on the same footing. I quite believe, my good friend, what you say, that you have no desire to hinder those about you from deriving pleasure from bee-keeping. But now let me put the matter in a little different shape.

Suppose this old man of whom you speak, "too feeble to do heavy farmwork," has 100 colonies of bees, his sole means of support, and these 100 colonies fully stock the pasturage within reach, would he desire, or would you desire for him, that a new man should come and plant another 100 colonies within 40 rods of his apiary? Would he want him to come with 50? would he with 10? And yet, as matters now stand, he could do nothing to prevent it.

CLASS LEGISLATION.

Several, like W. W. Maltby, on page 66, object to class legislation. What is class legislation? As I have always understood it, it is legislating in favor of a certain class as against one or more other classes. For instance, I knew a law in an Eastern State making it a criminal offense for a party other than a railroad official to sell part or the whole of an unused railroad ticket. Here was class legislation in favor of the class of railroads and against the class of travelers. I think you can hardly have class legislation without having at least two classes—for and against whom discrimination is made. But in the case of the desired bee-legislation, *against* whom is the discrimination? No one except bee-keepers cares a fig who occupies a bee-range, only so that the nectar be gathered at the least expense and sold at the lowest price. The man who owns an acre of ground or a thousand acres, but is not a bee-keeper, cares nothing about whose bees forage upon his land; only if he is intelligent he will be anxious that *somebody's* bees shall be there in sufficient number to benefit his growing crops. So as no class is legislated

against, I can not see how it can be called *class* legislation.

So, Brother Maltby,
If you can earn your salt by
Keeping bees in skeps,
Don't take any steps
To hinder legislation
In this here nation.

And now, good friends, a word in closing. I suppose you are tired of this controversy, and I am sure I am. Controversy is not at all to my taste, and in the present case I have the uncomfortable feeling that, by advancing my views, I have lowered myself in the esteem of those whose good opinion I highly value. But those views seemed to me in accordance with right and truth, and the greatest good to the greatest number. They still seem so. Here is the broad field covered with nectar in which none but bee-keepers are directly interested, and it seems to me better that each one should purchase and own his own field, moving together harmoniously, than to have struggles and dissensions, at a loss to all concerned, thereby keeping some out of the field by the uncertainty of the business. Time alone will tell whether I am a wild schemer or simply a little ahead of the times. I confess to entire error of judgment in one respect, for I thought the mass of bee-keepers would be with me as to the desirability of legislation, whatever might be thought of its feasibility. To my great surprise, all seem to have the opposite views; and as matters now stand, it seems that valuable space has been wasted in the discussion; and yet, in some way, good is always apt to come from an honest effort to get at the truth. I am very grateful to Mr. Root for the space allowed me, and for his evident desire to let me have fair play, and will now get back to other subjects where I shall not feel so lonesome.

C. C. MILLER.

Marengo, Ill.

FOUL BROOD.

ARE WE TO BLAME IF IT APPEARS IN OUR APIARIES?

FRIEND ROOT:—In your comments on my article on page 49, you say that a bee-keeper has no business having foul brood in his apiary, and so need not calculate on it. Perhaps not. Perhaps, too, he has no business having sickness in his family, and so need not calculate on ever needing a doctor, or having to use remedial measures. Some things, sometimes, may be prevented; other things, at other times, must be endured—or cured. Nobody should sit down with folded hands, and allow misfortune to overwhelm him, without an effort to prevent it; but nobody can prevent misfortune from overtaking him. To a large extent we have our fate in our own hands; but to a still greater extent we are at the mercy of circumstances, and subject to an overruling power.

If you meant to say that a bee-keeper has no business to allow foul brood to *remain* in his apiary, perhaps I can agree with you. You may mean to say, that foul brood originates only through some fault or negligence on the part of the bee-keeper. It may be so; I can not believe it. Ponder the matter as I may, I have never been able to see how any act or neglect of mine was instrumental in bringing the disease into my apiary, and I confess I have not the least idea what caused it. At the time it started, it seemed to me that it must have been caused by

the brood becoming chilled; but I do not believe it possible for the disease to originate that way. So far as I can see, there is not a bee-keeper in the land, especially if his apiary is within bee-flight, or, perhaps, within half bee-flight, of where there is or has been foul brood, that is not liable to have his bees attacked.

As to the Heddon hive, I readily admit that, under other circumstances—say in a different locality, with a different race or strain of bees, a different season, or a different system of management, I might have found my brood-chambers full of brood and empty of honey at the close of the honey-flow. I should have said of the screws, too, that I boiled a number in paraffine, and that these worked better than the others, though it is not a week since I twisted the head of one of these into splinters in trying to unscrew it, using flat pliers to twist with. Your suggestion of galvanized screws is a good one.

I, too, can say amen most heartily to the growing interest in outdoor sports, not only for children, but among people of all ages. Tobogganing is one of the most healthful of the popular-amusement crazes; and if I had ever had any objections to it I think they would have vanished with my first slide, which was before I had written the article in question. You see, I write from experience.

Dayton, Ill., Jan. 25, 1887.

J. A. GREEN.

Thanks for the correction, friend G. When I said a bee-keeper has no business *having* foul brood, I meant, of course, having it remain; and I do think, that, if he has his eyes about him, as he ought to have, he should get notice of it at the very outset. My apiarist admitted that he knew of its existence a week or two before he called our attention to the matter at all. Now, had we commenced at the very first glimpse of it, I feel quite sure it might have been stopped before it got into more than one colony, for we would have promptly burned up every comb in the hive at the outset; and I would do this, even if I found something that looked even *suspicious*.

BUMBLE-BEES.

PROF. COOK TELLS US A GOOD DEAL ABOUT THESE FRIENDS OF OURS.

YOUR request, dear Mr. Editor, in Jan. 1st GLEANINGS, that I give the biology, or life-history, of our good friends the bumble (or humble) bees was not overlooked, but until now not a moment could I spare to speak a good word for these little philanthropists, whose kind offices are hardly appreciated.

It has been no uncommon thing for our students to keep hives of these bees. Frank Benton had several colonies on our college lawn when he was here as a student. My little Bertie has often had hives of bumble-bees on our back-chamber porch, and has enjoyed watching them and studying their habits, very greatly. Mr. Editor, would it not be a wise reform to encourage our children to look on insects, frogs, etc., with interest and admiration, and not with abhorrence? I believe I am doing my children a substantial benefit in encouraging them to study insects, birds, and even bumble-bees. I spent all of last week in lecturing before the Wisconsin Farmers' Institutes, and I urged everywhere that parents encourage their children to rear insects and watch

their wonderful transformations. How easy this is! The child has but to put a cabbage caterpillar, the so-called "cabbage worm," under a common glass tumbler, with a little of its food-plant, and all the life-changes can be easily watched. What an easy way to awaken the interest and inquiry of our children, and to keep them from the street-corner, the saloon, and the jail!

The only bumble-bee that lives over the winter, in our northern latitudes, at least, is the queen. Bee-keepers are not surprised at this. The apiarist often finds his bees all dead but a handful in spring, and among the survivors he is almost sure to find the queen. Occasionally she is the only bee that survives a long journey. So, too, with bumble-bees, the queen possesses the maximum of vital force and endurance. I do not know whether the old bumble-bee queens that have done duty the previous season live over winter or not. Very likely some of them may. However this may be, the young ones certainly do.

In spring these large queens commence operations. As the workers have all succumbed to the rigors of winter, we can easily understand why we see so few bumble-bees in early spring, and why those that work so merrily upon the lilacs, dressed in their shining robes of yellow and black, are all so large. The queen finds an old mouse-nest, or some other convenient miniature cave under stone, board, or clod, and there stores a mass of pollen on which she lays her eggs. The larvæ develop much as do the immature hive-bees. When ready to transform to pupæ, they coat their cells as do the hive-bees, with a glue-like fluid which serves as a close cocoon. These cells serve afterward as honey-cells; and though big and clumsy, even more so than are the queen-cells of the honey-bee, yet in truth they are really much like them; that is, they are strengthened with wax exteriorly, and lined with a glue-like cocoon interiorly. This style of a cocoon is well shown in melting wax by use of the solar wax-extractor, as with the honey-bee's cocoon it contains very little silk, but is largely composed of a hardened glue-like substance such as lines the cocoons of most moths.

Soon the queen has several companions, the workers, which now do the outside labor, so that the queen remains mostly at the nest. In July the queens and drones begin to appear. Some of the older writers tell of two kinds of workers in the bumble-bees' nests—the large and small. It is likely that their large workers were these young queens. The drones are longer than the workers, and smaller than the queens. We often see these drones in late summer. As a boy, I called them stingless bees. No wonder. In August the bees pair. I once saw a drone and queen bumble-bee *in copulo*. They fell in the path before me, and the queen pulled away from the carcass of the drone, which surely had sacrificed its life in the performance of its duty. These young queens are the survivors of winter, and are the perpetuators of the species. The bumble-bees do not swarm, so that by July and August the nests are large and populous, and so the red clover, which depends for the most part upon bumble-bees to insure its fertilization and seeding, is fairly swarming with these valuable assistants of the farmer, upon which he depends for the seeding of one of his most valuable field crops.

Darwin was the first to show by elaborate ex-

periments that clover is dependent upon bumble-bees for full fertilization and fruitage. Dr. Beal, my colleague here at college, has experimented for years in the same line. He finds that clover covered with gauze will seed only partially, unless bumble-bees are caught and put inside the gauze. In this last case, the bumble-bees work upon the flowers, and a full yield of seed is secured. Dr. Beal has suggested to me that I experiment to learn how the queen bumble-bees may all be preserved through even our most severe winters, that our farmers may secure each year the fullest benefit from their valuable labors. Could we have bumble-bees early in the season, the first crop of our red clover would seed as abundantly as does that of white and alsike clover. These latter do not depend upon the bumble-bees, but attract and are fructified by the more numerous hive-bees, which swarm out in force, even in the early spring.

Agricultural College, Mich.

A. J. COOK.

But, friend C., don't the Italian bees, at least in a great measure, take the place of bumble-bees in fertilizing red clover? It seems to me that I find a great many more Italians on red clover than I do of bumble-bees; but perhaps they do not do the work as effectually. Is that why you speak of encouraging their propagation? Although you do not say so directly, I infer there is a kind of bumble-bee abroad in the fall of the year, that does not sting. If one could learn to tell which are drones and which are workers, by sight, we could tell when to run and when not to run. I presume, however, the drones would never show fight.

SEPARATORS.

FRIEND HEDDON ON VARIOUS MATTERS.

FRRIEND ROOT:—As I have many topics to write about, and you like short communications, I see no other way than to leave out the whys and wherefores and ask your readers to take my word for it when I give you the results of my experiments.

I have used both wood and tin separators, of various widths, for over ten years, and with sections whose tops and bottoms are $\frac{1}{8}$ thick, and whose bottoms are $\frac{3}{8}$ narrower than the sides (and I greatly prefer this $\frac{3}{8}$ difference). I have found separators $\frac{3}{4}$ inches wide just a little too narrow. I am making them $3\frac{3}{4}$ plump, to make sure of no elongated cells. I want to say to Dr. Miller, that the most skillful manipulator—one like Hutchinson, who can get beautiful straight combs without any separators—will have an ocean of trouble with separators $2\frac{1}{4}$ in. wide. I prefer tin to wood. I have used the tin T super, and it is, with all its objections, about the only practical arrangement for the use of separators without wide frames; but when I use separators (and I shall) I think I prefer the one-story, reversible wide frame.

HALF-POUND SECTIONS.

I have been reading our editor's talk about Mr. Wright, of Albany, and his half-pound sections. Do you forget that I have been one of the pioneers in using half-pound sections? Allow me to refer you to pages 5 and 27 of *A. B. J.* for 1883. During and since that year we have produced many thousand pounds of comb honey in half-pound

sections. We have tried five or six different widths, lengths, and thicknesses, and also some quarter-pound sections. We can get just as many pounds of honey stored in the smallest as in the largest sections in use. We have settled on the following size: $4\frac{1}{4}$ high x 2 13-16 long x 7 to the foot wide, between separators; six of these will fit in the same wide frame that takes four $4\frac{1}{4}$ x $4\frac{1}{4}$ x 7 to the foot sections.

For the past four years we have kept these constantly at retail in our stores, besides the $4\frac{1}{4}$ x $4\frac{1}{4}$ -pound sections; and while the latter sells by the pound at 16 cents, the former have always retailed at 10 cents each. Our stores sell about three times as many pounds of the large as of the small sections. Our large sections average a little less than 1-lb., while the small ones average a little more than half a pound.

PRICE OF HONEY.

I want to thank you for your foot-notes at the close of friend Hutchinson's article on page 102: "12 $\frac{1}{2}$ cts. per lb. wholesale," and 16 cts. per lb. to the consumer, is where I want to see good bright comb honey rest in the future. Did you ever think that grocers will work hard to hold honey up to "a penny an ounce," simply for convenience in selling the varying sections? A section weighing 14 ounces sells for 14 cents. If you want to know how much it is worth, with the price at 14 or 15 cents per lb., you can telephone your schoolteacher. Did you ever think of this? Simply on this ground alone I have held the retail market up 2 cts. at least. I say 16 cts. at retail, leaving $3\frac{1}{2}$ cts. for freights and all middlemen.

Our pound sections should vary from 1 lb. to less, never more; 16 oz. should be the maximum. You see the reason. They should be sold for just what they weigh. The $4\frac{1}{4}$ x $4\frac{1}{4}$ x 7 to the foot, with separators, is just the thing for these weights, and that thickness I find most perfectly adapted to the instincts of the bees. Quick sealing, smooth finishing, and more perfect combs, all favor this thickness here.

REPLY TO FRIEND DADANT.

Surely all will know that I wrote, or meant to write, 18, and not 28 years. However, the word *we* does not necessarily nor logically include myself. My argument would be just as true and faithful to the facts had I kept bees but two of the 18 years that my brother bee-keepers have been "introducing" extracted honey to consumers.

Mr. Robbins' article on page 94 is true to life, as I have found it, and fully answers Mr. Dadant. If it were possible I should like to believe Mr. Dadant's theory about the introduction of honey, but I should really like to feel that we are going to get it "introduced" before I die of old age. As I am unable to see that he has answered my article, or sustains his point, I will let it drop here.

REPLY TO FRIEND GREEN.

Several have written to me, asking what I have to say in reply to friend Green's reported partial failure with my new hive. I have only to say, that he did not get them of me, and that I believe they were not properly made; that there is no need of any of the failures he mentions; that glue does not bother us as much as with the L. frame; that, when the hives are properly made, the screws will always support the frames when inverted; will always turn at will, and are infinitely superior to any metal screw that can be made. After three

years' experience I can clearly see the causes of his partial failure, but will not occupy space to describe them here.

JAMES HEDDON.

Dowagiac, Mich.

PEDDLING HONEY TO FARMERS.

EXCELLENT HINTS IN REGARD TO.

READING Mr. J. B. Colton's article on page 93 prompts me to give my experience in peddling and disposing of honey. I have found a home market for my whole honey crop of 8000 lbs., with the exception of a few special orders from a distance, at an average of 8 cts. per pound.

In finding a home market, it seems to me a great mistake is made in taking it to the towns. There is always plenty of honey in town, but a dearth of it in the surrounding country. It is also a mistake to put it in the stores, to be sold on commission. The retail price is higher than consumers like to pay, and this prevents people from eating honey, except as a luxury. I have worked up a splendid home trade among the farmers, and find that they are the best customers. I left no honey in stores, to be sold on commission, neither would I advise any one else to do so. My honey is all extracted; and in selling it I am always very careful to tell the purchaser whether it be of the 1st, 2d, or 3d quality. There are as many grades of honey as of sugar, and one great mistake is made in selling for a first-class article that which really is not, thereby taking advantage of people's ignorance, and driving a sharp bargain, perhaps.

First class extracted compares favorably with comb honey of the same kind in flavor; but if it be of the first extracting, and some old honey is mixed with it, the flavor is changed, and some one, no doubt, will compare it with the comb honey, and then declare there is something wrong, and won't buy any more of it. The producer should know better than any one else the quality of his honey, and it is imperative that he represent it exactly as it is. He will gain the confidence of his customers, and lose nothing by it. As a rule, the majority of people will not go to any place to buy honey; but if it is brought to their doors, and they are allowed to sample it, they will buy much more readily. I have found peddling in town up-hill business. Among the well-to-do farmers, I have sold the bulk of my honey in 25 and 50 lb. lots, at 8 cts. per lb., and for smaller sales, 9 cts. As an instance, I sold, in six consecutive houses, 80, 25, 53, 40, 25, and 37 lbs., or 260 lbs. in all—all I had with me, and I have frequently sold a barrel in half a day. Next year I intend to sell all I raise, more easily than I have this.

For actual use in the family, I sold to one, 180 lbs.; another, 145 lbs.; and to quite a number, 100 lbs. Had I sold it at 10 cts., I could not have disposed of much; but at 8 cts. it is used instead of syrups.

Now as to delivery. In the fall I loaded a barrel on a spring wagon, and, using a honey-gate, I drew it off in any convenient vessel in the winter. The honey was taken out of the 50-gallon storage-barrels, and warmed so as to take out the granulation, then drawn off into 50-lb. kegs for convenience. This winter, most of it was sold in the keg, the keg being reserved for next season's use.

By way of caution, let me say, do not sell granulated honey except to old customers. Better make a warming-pan of galvanized iron that will cover the entire top of a stove or arch, and warm it over. If it is then drawn into kegs or other vessels, and made air-tight, it will keep a long time without granulating, and can be disposed of to much better advantage.

A great many people think that candied honey has glucose in it, and it is almost impossible to overcome that idea. Always be sure to tell them that it will candy, and also to keep it out of the cellar.

ROLAND SHERBURNE.

Lone Tree, Ia., Feb. 14, 1887.

PEDDLING HONEY A SUCCESS.

HOW THE BROWN-EYED BETTER HALF BEAT THE OTHER HALF.

AFTER reading friend Colton's article on page 93 I feel like giving my experience on peddling honey. By consulting our book I find we have produced and sold, during the past few seasons, about 12,000 lbs. of extracted honey. Our honey is all put in 58-lb. kegs, which have been waxed. After getting it all in kegs, and before it gets thick, we do our peddling. With horses and buggy and large bottles we go out through the country and stop at every farmer's house that we consider sure pay, and let them taste our finest clover honey, stating that we have it in kegs just the right size for family use, and that we will deliver the next day. Now he will say he has no money at present. Our reply always is, that it makes no difference at all about that, he can pay when he pleases, which most of the time will be next day. The next day we deliver the honey sold the day before. The kegs are all labeled with our name and candying notice.

Now, to give you an idea how fast honey can be sold in this way, I will say that, on my first trip, I sold in one afternoon 60 gallons. "Ah!" I think I hear you say, "there can't be much honey in your neighborhood." Well, I have just ascertained that there has been no less than 80,000 lbs. produced during the past season by nine bee-keepers within eight miles of us. Now don't say that I am an expert peddler, for that brown-eyed woman whom Belle and Charley call "ma" took it in her head to see what she could do this fall, and she drove her own team, and sold, in one short afternoon, eight 58-lb. kegs, averaging over one keg an hour; and I was told next day, while delivering, that I was nowhere, compared with my "better half."

In conclusion I would say, put your honey in kegs well waxed; never charge for kegs, but get them back when you can; don't scold or look cross if kegs or hoops are lost. Never deliver the honey while selling, as you will not sell more than half as much, as you will find by trying; don't peddle in towns, except by the keg; don't think, because you go over a route this year it will do for next year; never change the price during the season, if you can avoid it; but if you should find it necessary to lower your price, promptly notify all who have bought of you by the keg that you have placed the difference to their credit. Our 4000 lbs. of this season is all sold, and we have had several calls for more. Now, Mr. Root, I can not help but think that, if all our bee-men who can would do this way,

our markets would not be so overstocked, and prices forced down so low. W. W. McKEE.

Dyersville, Ia., Feb. 12, 1887.

We are exceedingly obliged to these two friends for the good suggestions they have made in retailing honey. To be able to sell our honey crop is half the secret of our chosen pursuit. We should be glad to hear from others on this subject, whether their success has been good or ill. We all want to know how, and there is no better way to get honey introduced into families.

REPORTS ENCOURAGING.

WHAT WAS DONE WITH A NUCLEUS.

I WILL furnish you a report from the nucleus bought of you last spring. I increased naturally to 4 good strong colonies, all fine bright fellows, and took a quantity of honey. They are now well provided for, and snugly packed away for the winter, all doing nicely. I have, besides, 8 hybrid colonies in good condition.

Jan. 27, 1887.

M. G. BAXTER.

FROM 37 TO 70, AND 5000 LBS. OF HONEY.

I commenced the season last spring with 37 stands, increased to 70, and took 4500 lbs. of comb and 500 of extracted honey, nearly all from white clover.

Winthrop, Ia., Jan. 25, 1887. E. P. BRINTNALL.

A GOOD FLY.

Bees had a good fly Jan. 20. Only one colony dead out of 146. Two more were in bad condition. I united them, which leaves me 144 stocks, most of which are in first-class condition. A. N. DRAPER.

Upper Alton, Ill., Jan. 31, 1887.

FROM 9 TO 35, AND 1035 LBS. OF HONEY.

I started in last spring with 9 colonies; increased to 32; got 1035 lbs. of comb honey. My bees are all in good condition, with plenty of honey. They are Italians.

W. M. SWEANEY.

Sandyville, O., Feb. 7, 1887.

FROM 4 TO 9, AND 600 LBS. OF HONEY.

I began last spring with three full colonies and one five-frame nucleus. I increased to nine colonies, and took 600 lbs. of honey in pound sections. The nine colonies went into winter quarters with ten full frames each. All of my combs built last year were built on full sheets of wired foundation.

Greenfield, Ia., Feb. 7, 1887. J. E. BROOKS.

FROM 88 TO 109, AND 24,000 LBS. OF HONEY—AN AVERAGE OF 272 LBS., SPRING COUNT.

My crop of honey was the best the past season that I ever made. I secured 24,000 lbs. from 88 colonies, spring count, and increased to 109. Between 18,000 and 19,000 lbs. of my crop was white honey, the rest honey-dew, or "black-jack," as we call it here. This honey was all extracted. No feeding was necessary for winter. My crop in 1885 was 3000 lbs., and I fed 1500 lbs. of it, spring and fall.

Farley, Iowa, Feb. 1, 1887.

JAS. SCOTT.

Friend S., you have given us a rousing report. Now we should like to know something about your locality, and also by what plan or system you managed to secure such

a large yield. Did you do the work alone, or did you employ help?

HEALTH IMPROVED BY ENGAGING IN BEE-KEEPING; HOLY-LANDS.

I have been keeping bees for fifteen years, but I took no interest in bee culture until 1882. I have been sickly for a number of years. I was advised to go into the business, which I did; and up to this date I have been wonderfully improved in health. My strain of bees is of pure Holy-Land stock. I have sold a large number of them at my home and abroad, and they give perfect satisfaction. They are docile in every way to work with. We have quite a number of bee-men in this part of the country.

GEO. D. RAUDENBUSH.

Reading, Berks Co., Pa.

NEW HONEY IN OHIO ON THE FIRST DAY OF MAY.

I commenced the season of 1886 with 11 swarms of bees; lost 12 swarms the previous winter. The season opened up very early. I saw bees working on apple-blossoms on Easter Sunday, April 25, 1886. I had something similar to the Hill device over the hives. I did not unpack my bees until pretty well along in May. I left the devices on the hives. I examined some of my bees May 1, and I found that one swarm had three or four pounds of honey built under one of the said devices, so we had new honey made in 1886, for supper, on the first day of May. Can any one beat that? I should like to hear from them if they can.

J. S. BARB.

Bristol, O., Feb. 15, 1887.

A BETTER SHOWING FOR THE ITALIANS; AN AVERAGE OF 50 LBS. PER COLONY FOR HYBRIDS, AND 260 LBS. PER COLONY FOR ITALIANS.

It takes about the same amount of work to sell the honey as it does to get it. My honey is nearly all sold at an average price of 6 cents for extracted, and 11 cents for comb honey. In the fall of 1885 I prepared for winter 124 colonies—90 in cellar and 34 in chaff hives. I lost one colony in a chaff hive, which was queenless in the fall, and sold 13. This left me 110 in all; of this number, 30 colonies were hybrids. These I moved to a place two miles from my home yard, so they would not bother me in my queen-rearing. They gathered about 1500 lbs. of comb honey in one and two pound sections, and increased to 56. I have sold them. Hybrids of the first cross are good honey-gatherers, but too energetic with their stings to suit me. I want no more of them. The 80 colonies that I kept at home were mostly nuclei, with young queens raised the fall before. It was surprising to see how soon they made good strong colonies. About June first I united 20 of the weakest with others that had poor queens, and used several colonies to make nuclei for queen-rearing, which left me about 50 strong colonies with No. 1 queens. I took from these colonies 11,000 lbs. of extracted honey and 1000 lbs. in combs, to feed next spring, and increased to 120. They were not black bees either.

G. D. BLACK.

Brandon, Iowa, Feb. 8, 1887.

Many thanks, friend B. It seems from the above that your Italians are not only gentler than the hybrids, but they gathered over five times as much honey per colony. Is it locality, manipulation, or the race of bees that made this difference? Perhaps friend Black or E. France can tell us.

REPORTS DISCOURAGING.

A TOTAL FAILURE, AND LOSS OF OVER \$300.

I STARTED in spring with 20 colonies—10 strong and 10 from very weak to medium; increased to 48, including five nuclei. I sold five nuclei—3 colonies, and about \$22.00 worth of queens, which left me 40 colonies, and I did not get 40 lbs. of honey from the 40 colonies in 1886. I am out about \$125 in honey, and about \$200 worth of time. We have had a failure in the honey-crop every year since I have been in the business. I wish you and Dr. C. C. Miller had got a law passed in 1882, prohibiting anybody but you two from keeping bees. I should have been about \$300 better off.

JNO. W. MARTIN.

Greenwood Depot, Va., Jan. 15, 1887.

A FIT SUBJECT FOR BLASTED HOPES.

Since I am writing, I will hand in my report for the past year. I had, to go into the winter of 1885, 14 stands in Simplicity hives. All came through strong and healthy. They commenced swarming early; increased to 27. Up to July 1st my bees did well; but from that time on they rather went back; and by the 1st of October there were scores of bees starved to death. I lost none, but doubled back to 24; took 150 lbs. of comb honey from 14 colonies, spring count, no extracted. My bees are all right yet, but rather poor for so many stands. If you have Blasted Hopes yet, you might put a few like me in for a while, just to see how we would like it.

Fairfield, Pa., Jan. 1, 1887.

J. A. KIME.

DID NOT PAY.

I do not like to report discouragingly for the bee-business, but I am afraid I shall have to, as my loss in experimenting during the past year will be over \$100.

J. C. FRISBEE.

Suffolk, Va., Dec. 27, 1886.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

HIVES PATENTED IN THE UNITED STATES—THEIR DECREASE.

WE are indebted to the *British Bee-Journal* of Feb. 3 for the following item in regard to the decrease in the number of patents on hives issued in the United States from year to year, up to and including part of 1886:

Your readers may not be aware that the specifications of patents taken out in all countries where there is a patent-law are filed and can be inspected in the library at the Patent-Office, Chancery Lane, without payment of any fee, simply by signing your name and address in a book as you enter. There is also a library of the scientific books of all countries.

After the little business I had at the Patent-Office this week was done I amused myself looking at the places and specifications of some of the American bee-hives. Seeing from the general indexes the great number of hives that had been patented in the United States I thought it might be of interest to your readers to know the number of patents taken out under the heading "bee-hives," not including extractors, feeders, smokers, etc., and I counted up the numbers, which are as follows:—From the commencement up to the end of the year 1873, 591; 1874, 22; 1875, 17; 1876, 22; 1877, 33; 1878, 33; 1879, 18; 1880, 12; 1881, 10; 1882, 8; 1883, 16; 1884, 8; 1885, 20; part of 1886, 6. Total, 816.

You will see that the year 1886 is not yet completed, but up to the latest returns the enormous number of 816 patents have been taken out for "bee hives." I examined about 30 of the most recent ones, and I should much like those gentlemen who consider that we get all our best ideas from America to spend a day there in search of ideas worthy of imitation, and I feel convinced that, whatever their opinion of the superiority of American appliances had previously been, he will go away surprised to find that any one would ever patent the rubbish he sees illustrated and described there. Upon inquiry of a patent-agent, I find a patent costs more than here, since the alteration of our patent-law.

JOHN M. HOOKER.

WILL THE THE NEXT YEAR'S HONEY CROP FOR CALIFORNIA BE A FAILURE?

I am in receipt of a letter dated Feb. 5, from my agent at San Buenaventura, Cal., stating that, up to that time, the rainfall in Southern California for this winter had been less than two inches. He says that, unless the rain comes soon, the California honey-crop will be a failure, as it takes from 10 to 18 inches to insure a crop of honey there.

While this is bad luck for our brothers across the continent, it may help to advance the price here; and let us try to make what is their unavoidable loss our material gain, and not be led to sell our honey at a low figure by those who wish to buy on the strength of "an immense crop in California."

Wyoming, N. Y.

G. W. STANLEY.

MOVING BEES.

Friend Root:—I wish to ask a little advice in regard to moving my bees. I have about 70 colonies to move about 225 yards south of their present location. The lay of the land is about the same; viz., sloping southwest, but the new location is much steeper ground, and the location of the hives will have to be in an altogether different shape than they are in at present. The bees are all in Simplicity-Langstroth hives, and contain from 4 to 20 frames each. What I wish to know is, how to move them with least loss, the best time in the spring to do it, and how to do it with the greatest ease. I am not very strong physically. If the editor, or any of the readers of *GLEANINGS*, have any suggestions to offer they will be thankfully received.

SUBSCRIBER.

New Brighton, Pa., Jan. 24, 1887.

It will be a little difficult, my friend, to have your bees adhere to their new location, unless the weather should favor you. If they can stand on the new site, say a couple of weeks, when there is no weather permitting them to fly, most of them will return to their new location. If, however, a warm day occurs shortly after moving them, so many bees will be lost it may be the ruin of a good many of your colonies. It is a very difficult matter indeed to move bees short distances, unless the weather happens to be favorable, as above. For further remarks on this subject, see "Moving Bees," in the A B C book.

IMPORTED QUEENS FROM BRANCONINI.

I have read your answer to Mr. Hudson, in the Dec. 1st No. 1, 1886, page 946. I thank you for what you have written of me, and please hear why you are quite right in so thinking. I do not charge more for Australia (proportionally) than for other countries, on account of difficulty of transportation. I have arranged, with my Australian patrons, one price for every town and every month, and the price is as low as possible. In fact, we

charge only 15 francs for every box; and the expense for sending to Australia, having to be paid beforehand, we pay about 4 francs on each queen. The boxes for that country must be larger, and contain a larger number of bees, a greater quantity of honey, and room for water—more than those for others. It is also to be remarked, that we receive orders of only 8, or at most 12 queens at once.

Bologna, Italy, Jan. 4. CHAS. BIANCONCINI.

The above gives the solution, friends. Queens to Australia must be prepaid for at least the greater part of the route.

LARGE HONEY-YIELDS.

In regard to immense yields by single colonies, frequently reported, I have been under the impression that they are stolen from other colonies. In the January 15th number of GLEANINGS, Emil J. Baxter mentions a yield of 560 lbs. he had from one colony. I believe his bees in that hive quietly stole the honey from other hives. This quiet stealing has been mentioned before in GLEANINGS. If those who have one or more of these big yielders will dust, with powdered chalk or flour, the bees of the big-yielding colony, and watch carefully, I believe they will find them the poorest lot in the yard. Try it next season.

E. E. EWING.

Rising Sun, Md., Jan. 22, 1887.

Friend E., I am sure you are entirely in the wrong. Bees may get a little honey, it is true, by this quiet way of stealing, but it is quite out of the question for them to get such a quantity as friend Baxter mentions. To get such an enormous crop, they would have to labor not only weeks but months, and that, too, on the high-pressure principle. When Italians were first introduced, it was suggested by a good many that the large yields were made by stealing from other bees; and men in our own vicinity, who ought to have good judgment, claimed that our Italians took all the honey from their hives as fast as the native bees could gather it. When these great yields are coming in, it is a very easy matter to follow the bees and see where they get it; and I believe that most bee-keepers are in the habit of finding out the source of these great accumulations. Dusting them with flour is an excellent idea, to enable us to identify them; but I think you will find them on the bass-wood-trees, in the clover-fields, or at some other honest and legitimate work.

BEEES TOO NEAR A RAILROAD, MILL, ETC.

In your issue of Jan. 15th I note a communication, page 50, in regard to the disturbance, in winter, of bees situated too near a railroad. I have had no experience myself, being two miles from the railroad; but last summer I visited the large flouring-mill of Mr. J. B. Ward, of our county, and he, being a bee-keeper as well as a miller, I was not long at the mill before I made inquiry about his bees, as I saw none in his yard or garden. His residence is situated but a few yards from the mill, just across and near the road, and the mill upon a high bluff of limestone rock on Stone River. Before he moved his bees near the mill he was a large honey-producer, and, withal, an experienced and scientific manipulator with bees. He informed me his bees did no good, made no surplus worth the trouble of taking, for two years, when kept near

the mill, and he moved them to his mother's, some two miles off, where they were doing well, although inconvenient for his attention. It was his opinion, that the roar of the mill, and tremulous motion the stones produced when running, disturbed them too much in their work. As the mill frequently runs all night, and also all winter, it may have been the disturbance, at these times, when they were not at work, that caused them so much uneasiness they did no good. He also lives near the line of the N. C. and St. L. Railroad.

W. P. HENDERSON.

Murfreesboro, Tenn.

MR. BINGHAM'S COMMENTS ON THE ARTICLE ON P. 44: A CORRECTION.

I have often recalled my visit to your beautiful home and shops with great pleasure. The multitude of incidents following my visit, and the Albany Convention, prevented my reading Jan. 15th GLEANINGS until yesterday, when lo! on page 44 an account of my wanderings confronted me. The report of my hive is all right; but that about the one filling of smoker making abundant smoke for use all day is rather "too good." I did not mean to be so understood. I probably said that the fire would not go out; but I did not mean that once filling with sound maple wood was sufficient for abundant use all day. The best thing that can be said of a Bm. smoker is, that it burns fuel fast—sufficiently fast to make enough smoke for *instant use without working the bellows*—just when there is no time to work up a fire. Smoke can not be made without fire. The old saying, "There must be some fire where there is so much smoke," proves to be correct in the case of bee-smokers, if they are always ready with a big puff of smoke to turn the heads of alert hybrids. I shall be glad to send you a smoker to try, and will do so soon.

T. F. BINGHAM.

Abronia, Mich., Feb. 11, 1887.

Thanks, friend B. I beg pardon if I misunderstood you in regard to the time your smoker will run without filling.

HOW TO WARM A CELLAR BY MEANS OF THE SQUARE CANS.

It is impossible to keep the temperature in my cellar up to 45° this winter without the use of artificial heat. I think the frost has penetrated the earth to a greater depth than usual. I have a 6-in. ventilating-pipe, 70 ft. long, laid 5 ft. below the surface; and the air, as it enters the cellar, is 38°, or 4° colder than it was last winter. As I did not like to risk a stove of any kind in the cellar, I thought I would try warming it with hot water. I do not know of a better way to handle the hot water than to have it in the 5-gallon square tin honey-cans. Four of them can be set on the cook-stove at once. I do not think that an open vessel would do, as the vapor would make the cellar too damp. The caps must not be screwed down tight when on the stove, or the cans will burst when the water boils.

The number of cans needed will depend upon the size and coldness of the cellar. My cellar is 14x14x 8½ ft., and contains 60 colonies of bees, and I find that two cans heated once in 24 hours will keep it about 4° warmer than it would otherwise be. The water will give out the heat gradually during 24 hours, so as not to excite the bees as the heat from a stove would. I think it is less work to carry the water up and down cellar than to tend an extra stove.

Brandon, Iowa, Feb. 12, 1887.

G. D. BLACK.

MYSELF AND MY NEIGHBORS.

Be kindly affectioned one to another with brotherly love; in honor preferring one another.—ROMANS 12: 10.

SOME of our neighbors are next door, others across the street, and still others are a mile away—may be eight or ten miles. It is the latter class of which I am going to speak this morning. The papers announced that there was to be a farmers' institute in a neighboring town. Across the country it is only ten or twelve miles; but as this is the season of Medina mud, we consider it easier to go perhaps 25 miles by means of three different railroads than to undertake to go "cross lots." If the three roads made connection as usual, I should get through in a couple of hours; but they did not connect, and there was a prospect before me of missing the proceedings of the first day. I could make the next station, however, by going two miles and a half on foot, and I very quickly decided to do this, for I have learned by experience that, when you are apparently brought up short, it does not do any harm to push ahead against obstacles, even if it must be done on foot. I had started out on this trip because it seemed as if God called me that way; and if it were in answer to this call, what anxiety need I have as to the result? My part was simply to say, "Here, Lord, am I, several miles from home, and my plans frustrated. What hast thou for me to do?" I looked back when I had hurriedly walked perhaps half the distance, and saw a fellow-traveler carrying two bundles. When you are wanting some opportunity to serve the Master, and you see somebody walking with two bundles, I think it is very safe to ask permission to carry one of them. Just a little while before, I had passed two other fellow-travelers. I slackened my pace for awhile, wondering if God had given me any message to them. Their principal comfort, however, seemed to come from the tobacco they passed back and forth, and evidently their tastes and mine were in different lines, so I courteously bade them good-day and pushed ahead. I almost always go ahead of other people when I walk, even if I am a small man. Well, now, this man with the two bundles walked even faster than I did. I found that he lived at our destination, where the farmers' institute was held. Furthermore, he is a devoted and earnest Christian; yes, and he is a banker besides. He gave me an account of the town of L., which was very interesting indeed; and as he is a Sabbath-school worker, and has the welfare of all the people at heart, we found many topics of mutual interest. Before returning home I formed an acquaintance with this man, which I shall remember as long as I live, and I shall always be the happier for it, because I know of one more who is hungering and thirsting after righteousness, and who is working and praying for the Master.

When we reached the station we were told there was no train for two hours and a half—no train of any sort. This cut off absolutely all chance of hearing friend Terry for

the afternoon. Now, although the station-agent told us there was no sort of a train, in about an hour a coal-train came along. A hot box obliged them to stop. The engineer said very flatly, however, they did not carry passengers "nohow." With some people this would have settled the matter; but it didn't with me, even when the conductor said the same thing. Did you ever know, my friend, how much difference it makes, in the way you approach a neighbor? I did not say any thing until I caught his eye, and then I good-naturedly replied, "My friend, I am very anxious indeed to reach L.; and if you will tell me what I shall do to get permission for you to carry us, I shall be very much obliged." His face softened a little, and he said I might telegraph to the superintendent, if I cared to. The telegraph operator did not seem to be very willing until we showed him some money, and told him we were ready to pay for all the trouble we made, whether he got us through or not. Now, please bear in mind that these neighbors of ours, especially at telegraph-offices and railway-stations, are often thoughtlessly hindered and annoyed, and very often by people who are not willing to pay for the trouble they make. A telegram came back immediately, saying, "Carry the passengers, providing they do not hinder in any way or manner." The conductor then told us if we were willing to jump off a little out of town, and foot it to the depot, we could go. Of course, we gladly consented. Now, I know from experience, dear friends, there are people who ask favors of this kind, and then demand to be set down at the depot, and other things of a like nature, in a way to hinder, more than they perhaps realize. The telegraph operator did not take any of our money for his trouble, after all. You see, we began to get acquainted a little, and he recognized us as business men who were accustomed to business, and knew better than to hinder, or even try to hinder, a railway train that must make its appointments.

A man that hath friends must show himself friendly; and there is a friend that sticketh closer than a brother.—PROV. 18: 24.

I can not tell you what a pleasant afternoon we had at the convention. Two or three hundred live young farmers sat at the feet, as it were, of friend Terry and of those who were capable of teaching improved agriculture, and drank in their words in a way that was very encouraging—at least to myself. When opportunity was given they took part, and I confess it greatly surprised me to find there were, within ten miles of my home, such a large number of really go-ahead, progressive young men—yes, young men and boys who had been putting in practice Terry's teachings in regard to potatoes, live stock, and even the adornment of their homes and farms.

Now, in this paper to-day, I wish specially to illustrate how much we lose by not interchanging ideas, or getting acquainted; and, by the way, one young friend at the institute gave us a most excellent talk on this very subject of getting acquainted with each other. He said one of his neighbors,

but a few miles away, gave him more valuable information on potato-growing in *one evening* than he had learned by experience in many years; and this man was ready to talk, and *glad* to talk, and yet the young man had never visited him before. None of us know what there is going on close at home; we do not know of the valuable information that somebody, even in the same room, might be able to communicate if we follow the spirit of the little text at the head of this chapter. Now listen. Of course, I was invited to stay over night with one of the bee-friends. While supper was being prepared I was left for a little time alone with an elderly lady who was also stopping there, but with whom I was, of course, unacquainted. I had simply been introduced to her, that was all. Books and papers lay on the center-table, and the question arose, Shall I look at the books, or shall I exert myself a little to throw off my natural bashfulness, and get acquainted. I was somewhat tired, and did not feel much like talking—at least, I did not suppose the other occupant of the neat little parlor would be interested in any of the topics that interested myself. It is true, if I had been practicing what I preach I might have very soon found out whether she loved the Lord or not; and if she did, as most women-kind do, of course there would be a common ground on which we could meet and feel mutually interested. The truth was, I had been kept in the audience-room a good many hours, and I naturally pined for the open fields; yes, I would have got out and run across the lots, even if it was frosty and after dark, had I thought it was the proper thing to do. God's voice seemed to indicate, however, that I should get acquainted, and I am very glad I overcame my weariness enough to obey. Pretty soon I found she had a son-in-law, who is one of the progressive farmers. This son-in-law had been investing a great deal of time and money in a vain attempt to thoroughly underdrain the marshy slope or sidehill near his barn. His mother-in-law was telling me how sorry she felt to see him try so many times, and fail, and his last bold attempt was the saddest of all, because he finally did *succeed*. This apparent contradiction is explained by saying that, when he got the water out of the sidehill, he dried up a spring some distance away, but *close to his barn*, where he had for years been watering his herd of choice Jerseys, his horses, and other stock. He had killed the bird that had for so many years stood in the way of his crops of potatoes and corn; but the *stone* that killed the bird knocked the bottom out of his nice well. At supper I asked my host how far away this son-in-law lived. He said it was about a mile. I begged to go and see him, but he told me it would be night before I got there. I fairly hungered for the open fields, underdrains, and swamp muck, and he finally agreed to go with me. When we neared the spot we heard the sound of babbling brooks, or gurgling water. By the way, running water has always had a fascination about it to my ears. Pretty soon there was more sound of running water,

and finally I was reminded of the words of Revelation, where John compares the voice of Christ which he heard, to the "sound of many waters." This young man, whose mother-in-law felt anxious about him, had, in his first experiments, been thwarted in his work by the tile filling up with black mud and silt. To overcome this he made large silt-basins, perhaps a yard square, and four to six feet deep. Into the silt-basins the tile emptied. Now, the inlet tile was perhaps six inches higher up than the outlet tile; and the result was, the water poured a few inches into the basin below. As these wooden curbs, or silt-basins, were scattered over the field, the sound of the pouring water under ground was what reached my ears and stirred me with enthusiasm. I could not very well see what the soil looked like, but I kicked into it with my foot, and took up handfuls. I did not need to be told it would raise potatoes. Occasionally the stalk of a big weed reared itself almost above my head. This weed had started after the drains were put in. All our friend needs is a windmill to lift the water up, and he will have a much better arrangement than he had before. The only trouble is, he has spent so much money in the drainage business that he feels as if he could not spare the cash for even a windmill just yet.

We went into the stables. He has a large tank to catch rain-water, and iron pipes convey the water to different parts of his barn, so that the labor of caring for his stock is comparatively light in the way of water during a season of plenty of rain. The barn is a model of neatness. There was one Jersey heifer there, not only nicer than any thing in the line of cattle-kind my eyes had ever rested on, but I did not know before that it was possible for a calf to be so pretty. I was strongly tempted to hand over the price of her, without thinking the matter over. It was only \$100, dear reader; but the owner had worked hard for his fine stock, and I like to see such men get a good reward. He, too, is a Christian, and day by day asks God's blessing on his labors; and even if the bottom of his well does drop out, and other like calamities occur, now and then, his faith in God does not waver. Why, dear friends, I do not know of any thing that I look forward to with more pleasure than a buggy-ride over to his place some afternoon, to see how his crops look on that beautiful soil, with the gurgling water prattling its story but a few feet distant in any direction. Now, this young friend is not alone. There are other young farmers all around him, enthusiastic over the matter of underdraining the Harrisville swamp that has been a great dreary waste for years and years; and during all the deliberations of the institute, I can not remember that there was a single unkind reflection. There were differences of opinion, but they were met in the spirit of our beautiful text:

Be kindly affectioned one to another with brotherly love; in honor preferring one another.

And they also showed forth most vividly the spirit of the verse just after our text—"Not slothful in business; fervent in spirit, serving the Lord."

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

ONE-STORY AND TWO-STORY CHAFF HIVES.

AS announced in the heading, I propose to chat with our readers in regard to the relative merits of the single-story and the two-story chaff hives. In discussing this matter, I do not wish to say any thing to detract from the merits of the old, true, and tried two-story chaff hive—the hive that has given such splendid results in wintering in almost all locations; but I feel constrained to point out some of the defects which have been named against it.

In the first place, when the upper story of the large chaff hive is filled with frames, there has yet been no feasible means of removing the brood-frames below without taking out singly each one of the wide frames. This has been considered one of its most serious defects.

Second, it does not permit tiering up more than two rows of sections high. It is sometimes necessary for us, in order to get the full benefit of the honey-flow, to tier up four or five sections high.

Third, the hive is rather unwieldy, especially for women and others who are not blessed with the average amount of physical strength.

Fourth, it is not interchangeable with the Simplicity hive. It requires a cover, cushion, and, in order to get the best advantages, supers peculiar to itself. However, it takes any of the brood-frames or wide frames fitting the Simplicity hives. Considerable thought has been expended as to how one or more of these defects could be obviated, but nothing really practicable has ever been suggested till the hive below was devised.

ONE-STORY CHAFF HIVE. HALF-STORY COVER.

The cut represents the single-story hive, which we have made and sold for the past six years; but as it was so much smaller we feared to recommend it very highly as a substitute for the larger hive. However, since that time the hive has proven itself to be a good one for wintering—at least, in this locality. Perhaps, then, it may not be out of place to mention some of its good features. You observe, that it is hardly more than a double-walled Simplicity hive, and might very appropriately be called the Simplicity chaff hive. It is perfectly interchangeable with the Simplicity hive and furniture; i. e., it will take both the flat or half-story cover, any of the Simplicity crates or supers, and the Simplicity body, the latter to be used for an upper story or for tiering up. When this small chaff hive has a Simplicity upper story on it filled with frames,

the brood-chamber is readily accessible by simply lifting off the upper story. The hive is also cheaper than the large one.

THE ONE-STORY CHAFF HIVE FOR WINTERING.

I feel just a little hesitancy in recommending this single-story chaff hive too strongly. If it will winter bees just as well as the two-story chaff hive, for the reasons named above, I should very greatly prefer it. However, in this locality, as far as tried, it has wintered colonies just as well, and in some cases it seemed to do better, than the two-story chaff hive. The style of this hive was devised by our foreman, Mr. Warner, some six years ago. A year before they were offered for sale, Mr. Warner tried 15 of these single-story chaff hives alongside of an equal number of two-story chaff hives. From the former he lost one colony during the winter. From the latter he lost three. This may have been merely an accident, but at any rate it goes to prove that the single-story chaff hive does just us well. One of our former employes has tried wintering four colonies in these for two or three years, and he reports that they wintered his colonies successfully. One of our sawyers, Mr. Will Turner, tried wintering four colonies in them last year, and he says they all came out in good condition. For the last four years we have tried wintering one colony in our apiary in this one-story hive, and every year that colony has wintered as well as the rest. Last fall I determined to try four of these one-story chaff hives under various circumstances. When I went through the apiary a few days ago I could not see that there was any difference in the way their colonies were wintering compared with the colonies in our two-story chaff hives. I have no doubt but that they will come out in the spring all right.

Now, there are other incidents I could mention; but the foregoing will suffice. But please bear in mind, that this is for only one locality; and while they might winter colonies successfully here at the Home of the Honey-Bees and vicinity, they might not do as well where the climate is more severe.

I will say from experience, right here, that these little hives will give better results in wintering if you put the Simplicity body on top, filled with chaff, than if you cover the brood-nest with a half-story cover only, in which a chaff cushion fits.

OUR BEES UP TO DATE.

One day last week, the weather being favorable, the apiarist and myself examined all of our colonies to see whether any of them might be needing stores, or whether any might need doubling up. Not one of our colonies has died up to date. Not only that, but they are in splendid condition. There were only three colonies in the whole apiary that seemed a little uneasy, but in other respects they appeared to be all right. The remaining colonies were in nice compact clusters; and when I pulled up the burlap and peered into them they really seemed stronger than when they were put into winter quarters last fall; at any rate, we found scarcely a dead bee at the entrance

of any of the hives, so that I believe we have now about as many bees per hive as we had when we put them into winter quarters. None of the colonies showed any indications of dysentery. In all the colonies examined, we found just one that we thought had better be united to another. The results up to date, certainly are gratifying, considering that, a year ago at this date, I found we had lost one colony, and two or three more showed signs of dysentery. However, we have two more months for the bees to pass through, so that we can not count our chickens just yet.

FOUL BROOD.

As I did not think it advisable to disturb the winter brood-nest, we did not pull our colonies apart to ascertain whether they had commenced rearing brood, so that we can not give any information yet as to whether foul brood has started, where brood-rearing may have commenced.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, MAR. 1, 1887.

And in thy seed shall all the nations of the earth be blessed, because thou hast obeyed my voice.—GEN. 22: 18.

THE number of our subscribers up to date is 6677, a gain of 253 within the last month. Many thanks.

ANOTHER SUGGESTION IN REGARD TO THE T SUPER.

DR. C. C. MILLER suggests using the loose T tins on top of the sections, as well as beneath, and he says the suggestion was given him by E. S. Armstrong, Jerseyville, Ill. Of course, this arrangement applies only to cases where the tins are loose. When the supers are tiered up it prevents the bees from putting the propolis in the space between the sections. Friend Armstrong suggests further, that with little trouble the whole lot of sections may be reversed if it should be desired so to do.

THE NEW JAPANESE BUCKWHEAT.

WHEN giving the illustration on another page, I omitted to mention that the buckwheat we have received from Peter Henderson is not quite as large as the cut shows it. There may be occasional grains as large as the picture; and, very likely, the grains when they are first harvested are larger than they are now. It is, however, considerably larger than any thing we have ever before had in the line of buckwheat. The European silverhull, advertised last season, is, as you may know, considerably smaller than the old silverhull. The size of the grain alone will make a ready distinction between our older sorts and either of the new ones.

TINKERING WITH BEES IN MARCH.

WE desire to enter a word of caution to some of our beginning bee-keepers. If you find, upon peering under the quilt or burlap of your colonies, that they are in nice compact balls, do not pull them apart; disturb them just as little as possible. If you have reason to believe that the colony is running short of stores, "heft" one end of the frames to see whether they are light in stores. If you find that their supplies are nearly exhausted, give them bee-candy, or, better still, a frame of sealed stores. This frame can be laid on top of the Hill device, just over the cluster. When the weather opens up warm you will have ample opportunity to pull the colony apart; but for three or four weeks yet, let the bees take care of themselves as far as possible.

GREEDINESS IN ADVERTISING.

It is not right, and I am sure it will not pay, dear friends, to declare in your advertisements that your goods are better and cheaper than any other in the world, and to the effect that people will get humbugged if they buy of anybody except you. I have noticed this particularly in our seed-catalogues. A seedsman broadly declares, and even employs pictures, to illustrate what enormous crops everybody secures who buys seeds of him. Then a counter-picture tells how the crops turn out if you purchase of any one *except* the advertiser. Now, I do not like this, even as pleasantly. Say, if you choose, that people who buy of you are generally successful; but don't, I beg of you, try to make it appear that all the world are cheats and liars, with just one exception.

CLOTH INSTEAD OF GLASS FOR HOT-BEDS, COLD-FRAMES, ETC.

A YEAR ago I was not very well pleased with the new water-proof cloth substitute for glass. Since then, however, I have learned to use it, and find that it answers a most excellent purpose when our heavy snowstorms and freezing weather are pretty much over. It must, however, be fastened to frames a good deal like the frames that hold glass, and these frames must be fastened down so they will not be blown away by the wind. After this is done it will keep off frost tolerably well, although not like glass; and as it permits the rain to go right through it, there is no need of handling the sashes, to get the benefit of warm showers. It also permits sufficient air to pass through, so that there is no danger of scorching the plants by the heat of the sun, even if you do not ventilate at all. Add to this, that it gives just about the proper amount of shade for plants newly set out, and it promises to be a great help in starting early plants for any purpose. It also stops the circulation of air sufficiently to keep the air and the soil just moist enough to encourage almost all kinds of vegetable life. It is offered at 3, 6, and 9c per yard, according to the quality, by the U. S. Waterproof Co., 56 South St., New York. The cotton sheets that I experimented with a year ago by painting with boiled linseed oil, are not what is wanted at all. The oil soon makes the cloth rotten, obstructs the sunlight, makes the cloth heavy to handle, etc. The plant-bed muslin mentioned above is the best substitute for glass; and although it is really superior to glass late in the spring, on accounts mentioned above, it can by no means take the place of glass for hot-beds or greenhouses in winter time, even if the manufacturers do advertise that it will.

THE T SUPER.

It is astonishing what an amount of correspondence has come up in regard to T tins and T supers since Ernest and Dr. Miller have been working at it; and, as usual, there seems to be some little feeling as to who first invented it. I do not suppose it will be possible to tell exactly, now; but you will find a picture of them in GLEANINGS for January, 1876, a little more than eleven years ago. I can not tell whether I got the idea from somebody else, or whether it was one of my own notions. But we made them of two pieces of tin soldered together, and also of one piece of tin folded to the proper shape. The crate there illustrated holds 24 sections. The tins were put in so as to form the usual beespaced between the top-bars of the frames and the bottoms of the sections. Perhaps we might mention, right here, that Mr. M. G. Chase, of Whittlessey, Medina Co., O., has been using these supers for the last four years. Our friends will remember that he is the gentleman who produced that nice section comb honey we have had occasion to refer to several times. Mr. C. has used them with the T tins stationary. He has also used, in conjunction with this T super, a wooden queen-excluding honey-board, not only for the purpose of excluding queens, but to prevent the bees from soiling the bottoms of the sections in his T supers. Our foreman, Mr. Warner, has just informed us that he made for Mr. Chase this wooden queen-excluding honey-board something over a year before Mr. Hutchinson described it.

SPECIAL NOTICES.

DISCOUNTS FOR ORDERS RECEIVED DURING THE MONTH OF MARCH.

REMEMBER, there is a discount of 2 per cent on goods of every description, on all orders received during the month of March. After April 1, no discounts for the month in which the order is received.

ORDER EARLY.

THE rush of business is just now coming on, and indications seem to point that we shall have as much or more business than we have had previous seasons. Our customers needing supplies would do well to order early. Bees seem to be wintering well all over the country, and their owners will soon be in need of more hives and fixtures.

PRICE OF WAX.

UNTIL further notice we can pay only 20c in cash, or 23 in trade, for fair quality of beeswax delivered here. The same will be sold to those who desire it, for 25c, fair average quality, or 28c for best selected. When you send us wax, be sure to put your name on the box, so that there will be no trouble in telling to whom to give credit.

FOUNTAIN PUMP, OR SPRINKLER.

In our last issue we gave notice of an advance in the price of these pumps, and an improvement on them. We have about 125 pumps of the old style which we will sell, as long as they last, at the old price. If you want to secure some at the old price, send in your orders early, as these will not last long, and there will be no more of them. The improved pump will not be ready for the market till about March 15.

LABELS FOR FRUIT-TREES, ETC.

We have just invented a process for making these out of our waste white basswood, so that we can furnish labels 3 inches long, $\frac{1}{2}$ inch wide, and $\frac{1}{2}$ inch thick, for only 50 cts. per 1000. Less than 1000 will be at the rate of 10 cents per 100. If wanted by mail, add 3 cts. per 100, or 25 cts. per 1000. These are notched for the wire, but no wire is put on. We

can fit them up with copper wire for 15 cts. per 100, or \$1.00 per 1000 extra.

NEW JOB LOT OF WIRE CLOTH.

We have just received from the manufacturers another lot of green wire cloth, a list of which you will find in our advertising columns. It is all first quality; each piece is nicely wrapped up in paper, and, most important to many of you, there are many small pieces just such as you want. If you wish to secure your choice of sizes you will have to order at once, for these small pieces always go off like hot cakes. The price is $1\frac{1}{2}$ cts. per sq. ft. in whole pieces; 2 cts. per ft. where we have to cut it.

ONE-STORY CHAFF HIVES.

For those who would like to know the prices of the one-story chaff hives, illustrated and described in another column, we append the following; viz.: One-story chaff hives, with half-story cover, as illustrated elsewhere, complete for comb honey, with metal-cornered frames, perforated zinc honey-board, enameled sheet, and a crate of sections with fdn. starters and separators, \$3.00; one-story chaff hive, nailed, painted, and stuffed, no furniture, \$2.00.

ONE-STORY CHAFF-HIVE IN FLAT.

Price of each in flat, \$1.20; price of five in flat, each, \$1.10; price of 25 in flat, each, \$1.00. Above price includes half-story cover. For further particulars, see page 19 of our new price list.

CIRCULARS RECEIVED.

The following price lists have been received at this office:

George E. Hilton, Fremont, Mich., a 4-page list of apianarian supplies.

T. A. Salisbury, Syracuse, N. Y., a 20-page list of apianarian implements.

W. W. Cary, Coleraine, Mass., 30-page list of bees, queens, and general supplies.

J. W. Shaw & Co., Loreauville, Iberia Parish, La., a 4-page list of bees, queens, nuclei, etc.

F. A. Snell, an 18-page list of apianarian supplies; specialty, Snell's Eclipse hives and furniture.

Geo. Wheeler, Norwich, N. Y., a 10-page circular of Simplicity and Langstroth hives, crates, etc.

O. E. Heacock, Barberville, Volusia Co., Fla., a 14-page circular of bees and queens.

Frank Boomhower, Gallupville, N. Y., an 8-page circular (large size) of poultry, and price list of bees and queens.

Smith & Jackson, Fillbury Center, Ontario, Can., a 20-page circular (large size) of bee-supplies; specialty, the Excelsior bee hive.

Dougherty & Wiley, 661 Washington St., Indianapolis, Ind., an 8-page circular, large size, of general supplies, bees, nuclei, hives, etc.

J. D. Goodrich, East Hardwick, Vt., an advertising sheet of general bee-supplies. Mr. Goodrich again sends out this year his sample package of sections and foundation. The latter is very fine.

Thomas Gedyne, La Salle, Ill., a 4-page circular of bee-supplies; specialty the German brown bee. The last-mentioned was printed at this office.

CONVENTION NOTICES.

The St. Joseph Inter-state Bee-keepers' Association will meet in the lecture-room of Unity Church, in St. Joseph, 9th St., between Edmund and Felix, on Wednesday, March 16th, at 2 and 7 P. M. All are invited. E. T. ABBOTT, Sec.
St. Joseph, Mo., Feb. 14, 1887.

10-INCH FOUNDATION-MILL FOR SALE.

A friend at Carson City, Nevada, has one of our improved 10-inch foundation-mills, with dipping-tank and boards, that has *never been used*, he having been taken sick soon after he received it. At our present prices it is worth over \$23.00. We will sell it for him at \$22.00 for the outfit complete. This is a good chance for some Western bee-keeper, who wants a mill, to save quite a sum in the way of freight charges. A. I. ROOT, Medina, Ohio.

PURE ITALIAN BEES FOR SALE.

In superior movable-frame hives. Frames $12\frac{1}{4} \times 12\frac{1}{4}$; eight frames each, at from five to six dollars per colony; or same in light strong shipping-boxes, 75 cts. less. Liberal discount on large lots. 4tfdb. DR. G. W. YOUNG, Lexington, Mo.

CAROLANAN AND ITALIAN QUEENS, BEES AND SUPPLIES.

Also B. Leghorns, P. Rocks, and Raspberries. 5-6-7d Box 34. J. W. CLARK, Clarksburg, Mo.

HASTINGS PERFECTION FEEDER.

After a trial of the **PERFECTION** you will use no other, for the following reasons:

1. Prevents Robbing.
2. Bees can not be drowned or chilled in reaching the food.
3. Bees can be fed at all seasons of the year without being disturbed.

Read the following:

The "Perfection Feeder," made by M. E. Hastings, is altogether the best feeder we have yet seen.

It combines all the good points of all the feeders we have ever seen, with none of their bad features. It simply is perfection. We have tried it, and we know we can not give it too high praise.

Editor Bee-Keepers' Magazine.

Send for sample by mail; to hold 4 lbs., 50 c.; 6 lb., 60c. Per doz., 4 lb. feeders, \$3.50; 6 lb., \$4.50.

5d M. E. HASTINGS, NEW-YORK MILLS, ONEIDA CO., N. Y.

The "Gilt Edge" Apiary offers Italian queens from imp. mother; untested, in April and May, \$1.25; untd, in June and after, \$1.00. Tested queens double above price.

Oh tell me! Oh tell me!

And I shall be so glad!

Do you know of some reliable man

Where fine bees may be had —

Gentle and fine Italians,

With industry and business combined,

Those that will work on red clover,

And never are behind?

Oh, yes! my friend; I'll tell you,

And I know they'll fill the bill;

You can get them of F. Boomhower,

And he lives at Gallupville.

He breeds fine poultry as well as fine bees; also ferrets, rabbits, and Jacobin pigeons. Finest flock of laced Wyandottes in America. Send postal for fine illustrated circular. \$50.00 worth of bees and stock to give away. Address

5d F. BOOMHOWER, Gallupville, N. Y.

A Year Among the Bees

BEING

A Talk about some of the Implements, Plans, and Practices of a Bee-keeper of 25 years' Experience, who has for 8 years made the Production of Honey his Exclusive Business.

A book of 114 pages, well printed, and nicely bound in cloth.

A. I. Root, in *Gleanings*, says: It is a plain, familiar talk about bees and bee culture. It starts out in an intensely interesting and taking way, and keeps it up all through the book.

Dr. J. P. H. Brown says: It bridges over a big vacancy in practical bee-keeping.

The "AUTOMATIC"

Is the only Honey-Extractor that reverses the combs all at once by their own weight. It will do three times more work, and do it better, than any other machine. It will extract from unfinished sections at the rate of 1000 to 1500 per hour, and not injure the comb. It will extract from new combs as rapidly as from old, and will not bruise them. It will hold the combs perfectly straight, and protect them on both sides. It will do its work rapidly and perfectly; gives entire satisfaction, and lasts a lifetime. It will carry 50 Bingham smokers or honey-knives inside the can, with no extra charge for freight; and as I can furnish these goods at Bingham's prices, both wholesale and retail, it will pay you to order them with the extractor. Send for circular, giving size of frame used, and get prices of machines. Address

HONEY COLUMN.

CITY MARKETS.

CINCINNATI.—*Honey.*—Nothing new since our last report. There is a fair demand from manufacturers for dark honey. And there is a quiet but fair trade for choice comb and extracted clover honey in square glass jars. There is a large supply of all kinds. Extracted honey brings 4@7c in bulk on arrival. Choice comb honey sells at 11@14c in a jobbing way.

Beeswax.—Demand is good. It brings 20@23c for good to choice yellow on arrival.

Mar. 12, 1887.

CHAS. F. MUTH & SON,
Cincinnati, Ohio.

COLUMBUS.—*Honey.*—Market dull; white clover is selling for 14@15c in comb; California, 10@12c; extracted, white clover, 14@15c; California, 10@12c. *Beeswax*, 23@25 in jobbing way.

Mar. 11, 1887.

EARLE CLICKENGER,
117 S. 4th St., Columbus, Ohio.

CHICAGO.—*Honey.*—Market without much change. A limited demand exists in a single case way. Best grades of white clover in 1-lb. sections, 12@13c; not choice, same size, 9@10c. Very light demand for extracted. Prices range 5@6c for best white; dark, 3@4c. *Beeswax*, fair demand at 23@25c.

Mar. 10, 1887.

R. A. BURNETT,
161 So. Water St., Chicago, Ill.

DETROIT.—*Honey.*—All grades of honey dull and lower, and sales not what they should be at present prices; best white, 10@11c. *Beeswax*, 23c.

Mar. 11, 1887.

M. H. HUNT,
Bell Branch, Mich.

ST. LOUIS.—*Honey.*—Our market is badly overstocked with honey of all kinds. Choice white clover will not bring over 10c in sections. Rough and broken comb 6@8. California, amber, in cans, 4@4½; sage 4½; white clover extracted, cans, 4½@5½; bbls., kegs, etc., 4@4½. Southern honey, bbls., 2½@3½. *Beeswax*, 21. Selected yellow on orders 25c.

Mar. 11, 1887.

W. B. WESTCOTT & Co.,
108 and 110 Market St.

KANSAS CITY.—*Honey.*—There is no change in quotations from our last report. All grades selling slowly.

Mar. 11, 1887.

CLEMONS, CLOON & Co.,
Cor. Fourth and Walnut Sts., Kansas City, Mo.

CLEVELAND.—*Honey.*—There is no material change in our market. Best 1-lb. sections, white, sell at 12½@13; second, 11@12. Buckwheat and dark, 9@10. 2-lbs. white, 10@12. Extracted, 5@6.

Mar. 10, 1887.

A. C. KENDEL,
115 Ontario St., Cleveland, O.

BOSTON.—*Honey.*—We have no change in prices to note. Moderate sales on account of bad weather.

Mar. 11, 1887.

BLAKE & RIPLEY,
57 Chatham St., Boston, Mass.

PHILADELPHIA.—*Honey.*—Same as last.

Mar. 11, 1887.

PANCOAST & GRIFFITHS,
242 South Front St., Philadelphia, Pa.

NEW YORK.—*Honey.*—There is a liberal demand for comb honey, and stocks are reducing quickly. We are entirely out of white honey. We quote: Dark, and buckwheat, 2-lb. sections 5½@6
1-lb. 6@7

California extracted, white sage, 5@5½

Amber 4½@5

Beeswax, steady at 23@24; receipts increasing.

Mar. 11, 1887.

THURBER, WYLAND & Co.,
New York, N. Y.

FOR SALE.—If any of the friends would like some nice white comb honey in 4½x4½ sections, in Root's 48-lb. shipping-crates, we have 500 lbs. for which we will take 12½c per lb., on board cars.

DISTURBING BEES IN WINTER.

FRIEND DOOLITTLE PROVES PRETTY CONCLUSIVELY THAT IT DOES NOT ALWAYS DO HARM.

OF late I have been wondering if we as bee-keepers do not talk and write a great deal that we really know nothing about, only as we have accepted it from the thoughts of others. All are aware, that we have been repeatedly told that bees should never be disturbed in winter unless they could fly at the time such disturbance was made; for, if handled or moved in cold weather, much harm and loss would occur as a result. As my mind goes back over the past, I recall these instances which go to prove that the above theory does not always hold true.

In the winter of 1869-'70 I purchased one colony of bees out of a lot of 30, from a neighbor living two miles distant. This was in February, and the bees had had no fly during all the winter previous. The roads were very rough at the time, but I was not content to leave the purchased colony where it stood, so I brought it home; and after letting it stand a few hours to quiet down I set it in the cellar. It came through to the working season in the best possible condition, not having a chance to fly till about the middle of April, while every one of the 29 colonies left died before the first of May.

Again, in 1875, about the middle of December, I moved my whole apiary from my former place of residence to where I now am, a distance of 75 rods, placing a part in the cellar, and leaving a part outdoors; and at no time have I had my bees winter better. Then the readers of GLEANINGS will remember the experiments I conducted two winters ago to get the temperature of the center of a clus-

ter of bees, during which process the colony experimented upon was frequently disturbed, and many bees were lost by being pulled out on the thermometer and otherwise, flying out during the disturbance consequent upon the many experiments; yet this colony, contrary to my expectations, came through in much better condition than many others not disturbed at all, and was the second one to swarm the next season, being third best of the whole apiary, as to honey-production.

Again, wishing to know more about the matter of disturbing bees in winter, and to ascertain other facts as well, if possible, I have this winter handled a colony of bees with the mercury at 3° below the freezing-point, taking out all the frames, and examining them the same as I would in summer. About the 25th of January I found I had two colonies that were beginning to get uneasy, and show signs of bee-diarrhea. Knowing that I must lose them I resolved upon opening one of the hives as soon as a moderate day came without wind, to see if I could find out the cause of the trouble. Such a day did not occur till the fore part of February, as our winter has been remarkable for high winds. I now proceeded to the hive, and, upon raising one corner of the quilt, I found the bees ready to boil out and fly. To overcome this I put the nozzle of the smoker in under the quilt and gave a few puffs which drove them back, and, by keeping smoke upon them I soon had the quilt off, with the loss of very few bees (perhaps half a dozen), for all which took wing were soon on their backs in the snow. Before touching the frames I waited a moment or two; and as fast as the bees from the inside of the cluster would come up to see what the trouble was, or to take wing, I would drive them back with smoke. They soon gave up trying to fly, when I proceeded

to handle them as I pleased, putting them all back as before, except that I set a frame of honey, from the outside of the hive, on each side, near the bees, as a precaution against starving. I also cleared the bottom-board of dead bees and dirt. It has been now nearly a month since this was done, and an examination to-day shows bees in fine ranges of comb in a semi-quiet state, while the other colony, not disturbed, are all dead, except a few bees in one space; so it would seem that the handling of this colony of bees proved beneficial rather than the reverse.

Now, do not understand that I recommend a general handling or disturbing of bees in winter, for I do not; but hereafter, if I think a benefit can be made to a colony by handling it, either to keep it from starving or otherwise, I shall not refrain from so doing for fear that I shall make matters worse. In all such departures from the regular beaten path we should always go slow, always using but a very small part of the apiary for experiment; and then, if wrong, no great loss can result.

Bees have had no chance of flying here since the first Wednesday in November, and are beginning to suffer from their long confinement, about one colony in five out of doors showing signs of uneasiness. Those in the cellar are in perfect condition.

Borodino, N. Y., Feb. 28, 1887. G. M. DOOLITTLE.

I am not surprised, friend D.; in fact, I presume many of you remember the experiment I have often mentioned, of bumping a hive every day all winter long, to see if the bees were alive. Of course, they were kept in the cellar, and they came out in the spring stronger than when put away. I think that the most of us are a good deal inclined to jump at conclusions, and to get notions in our heads.

LEGISLATION IN REGARD TO BEE CULTURE.

AND THE KIND OF LEGISLATION THAT MIGHT NOT PLEASE US.

WE extract the following from the *American Bee Journal* of Feb. 23:

That legislation which we mentioned last week as being sought to be made in Michigan is stirring up the bee-men there. Mr. S. Shoup, of Coloma, Mich., has sent us a copy of the bill. It was introduced by Mr. McCormick, and recommended by the Committee on Roads and Bridges. It reads as follows:

A bill to prohibit the keeping of bees in large quantities near any public highway or dwelling-house not owned or occupied by the keeper or owner of such bees.

SECTION 1. *The People of the State of Michigan enact,* That it shall not be lawful for any person to keep to exceed five stands of bees within 25 rods of any public highway, or less than 25 rods of any dwelling-house not occupied by such keeper or owner of bees.

SEC. 2. Every keeper or owner of bees neglecting or refusing to comply with the provisions of the preceding section after due service of written notice, shall be subject to a penalty of \$5 for each day's neglect or refusal, which may be enforced and collected before any court of competent jurisdiction.

Mr. Geo. E. Hilton, President of the Michigan State Bee-Keepers' Association, writes thus:

This bill, should it pass, would be a great calamity to our pursuit, and to the State as well. As it is almost a necessity to have our bees reasonably near both, and it simply means the extinction of the

honey-bee, and a terrible calamity to the horticulturist, I feel it my duty to urge every bee-keeper in the State to write to their Senators and Representatives, asking their assistance in defeating any such bill. Just deluge them with letters. Use the best arguments at your command to prove that our rights are being infringed upon, and that we are alive to our interests, and demand our rights.

Friend Newman suggests that Prof. Cook is the man to look after this, as he is near to the State capital, and as his name itself would have sufficient weight to cause the matter to be carefully looked into.

Since the above was in type we find the following from the pen of Prof. Cook, in the *American Bee Journal*:

The "Bill to wipe apiculture out of Michigan" (that is my title to it) will never pass, and will probably never be called up. Michigan aims to foster her important industries, and not to throttle them. Such a bill could not get a dozen votes in the Michigan Legislature. Still, I hope every bee-keeper in Michigan will write to Hon. Mr. McCormick, Lansing, Mich., urging him to withdraw the bill. It will serve to enlighten him and others as to the status of this business.

Later.—The following comes to hand from friend Bingham, which settles the matter.

STATE OF MICHIGAN,
REPRESENTATIVE HALL.

T. F. Bingham, Esq.:

Yours in regard to House Bill No. 89, relative to keeping of bees, is received. In reply, allow me to say the bill came up yesterday in the general assembly, and I had it tabled. It will not be called up again. I have no intention of legislating the bee-business out of the State. The bill was introduced at the request of a gentleman who has been bothered, I presume, by some one's bees.

Lansing, March 5, 1887. JAS. W. MCCORMICK.

GILBERT M. DOOLITTLE.

A SHORT SKETCH OF HIM BY A NEIGHBOR.

G. M. DOOLITTLE was born April 14, 1846, near his present location, in the town of Spafford, Onondaga Co., New York. His parents were natives of Connecticut, and moved to this State a few years before he was born; hence the thoroughness, energy, and activity of the "Yankee" are largely manifested in the subject of this sketch. From his earliest youth Mr. D. has been an admirer of the busy bee, taking great interest in them when kept by his father. Later on, nearly all the bees in this section of country perished with foul brood, so that from 1856 to 1862 a hive of bees was a rarity. After this the disease seemed to abate, so that, in 1868, bees were quite common again.

As 1868 was a splendid honey season, bee-talk was rife in this locality, which again brought to life old ambitions which had been crushed out by the former loss by disease among the bees, so that the spring of 1869 found Mr. D. with two colonies of bees of his own, as the starting-point to his present apiary. Wishing to know for himself all of the minutiae of this (to him) interesting pursuit, he procured nearly all the bee-books of that day and subscribed for the bee-papers. As his ambition led him toward the practical side of bee-keeping, Quinby's *Mysteries of Bee-Keeping Explained* was his favorite, the pages of which were as familiar to him as a nursery rhyme. His intense desire to learn and investigate the bees in every particular has been such that he has dreamed of them at night, and thought of them in his working hours to an almost absorbing extent, and to-day he is

still a student, believing that there are many unexplored regions, and much room for the deepest thought, even on the practical part of this pursuit.

In the first few years of his apicultural study, Elisha Gallup, then living in Iowa, gave him by letter much practical instruction, which, together with Gallup's articles in the different papers of that time, so grew into his life that he went by the name of "Gallup" among bee-keepers about him for several years; and to-day he is often heard to say that there never has to his mind been a greater man in the realm of bee-keeping than E. Gallup. Gallup in his private letters laid great stress on good queens, claiming that around the queen centered all there was in bee-keeping, which has caused the subject of this sketch to study along

for Mr. D. has never done "any thing in a corner," but, on the contrary, has given all of his successes and reverses, together with the most of his plans and methods, to the public as freely as he would to his family, always realizing that it was largely through the philanthropy of others that he has attained the success which he has achieved. N.

I will add to the above, that we have few bee-keepers now in the world who are as conversant with the contents of all of our bee-books and bee-journals as friend Doolittle is. A great many go into the bee-business, and sooner or later drop it and turn their attention to something else. Even our energetic and enthusiastic friend E. Gallup, mentioned above, is now doing

G. M. DOOLITTLE, BORODINO, N. Y.

the line of queen-rearing to a much larger extent than any other part of this interesting pursuit, and it is believed by him that much of his success as a honey-producer has come from this, and his ever-anxious care to get the hive filled with brood at such a time that there would be multitudes of field-bees at the opening of the honey-harvest.

In 1870 Mr. D. wrote his first article for publication, at the request of W. G. Church, editor of the *Apiculturist and Home Circle*, published at Mexico, Missouri. Although a poor penman and scholar, he received many encouraging words from Mr. Church regarding his articles, which gave him confidence, so that to-day there are few who write more largely about the "little busy bee" than he. The rest of his bee-keeping life is familiar to all the readers of *GLEANINGS* and other bee-papers,

little or nothing with bees, if I am rightly informed. This is, in some respects, unfortunate, because there are so few perfectly familiar with what has been already done. As an illustration, our boys here in the office, Ernest and John, are perhaps better posted in regard to hives, etc., just now, than I am; but they know little or nothing about the experiments that were made, and that our bee-journals were filled with, some 15 or 20 years ago. Friend Doolittle has stuck right to the bees unflinchingly in all these years. If somebody commences to make a great ado about his new invention that is going to revolutionize, etc., friend Doolittle can say to him, "My friend, this matter was discussed and talked over and experimented with more than ten years

ago; in fact, we had so much of it that the editor shut down on us, saying the subject was exhausted." Very likely our young inventor may demand the proof, and friend Doolittle is the one who is able to take down his old back volumes and put his finger right on the spot. This gives him a power and ability possessed by few of our present writers. May God spare him many years yet, to guide and direct the new generations who are constantly coming on to the stage, and—wanting to know, you know.

TIME OF TAKING BEES OUT OF THE CELLAR.

A FEW TIMELY HINTS FOR THOSE WHO HAVE BEES IN THE CELLAR.

I THINK I never regretted taking bees out of the cellar in the spring too *late*, but I have regretted taking them out too *early*, more than once. If bees appear a little uneasy, and a fine day comes, there is a strong temptation to hurry them out, even if there is time for considerable cold weather. In 1872 I took out my bees Feb. 22, in bad condition, about half of them alive. They had been fed late, which, perhaps, was at the bottom of the trouble. They flew a little, but it was not warm enough for a general cleaning, and soon after there came a cold storm with snow a foot deep, and by April I had only two colonies left out of the original 50. I suspect more would have lived if they had been left in a month or two longer.

Some have expressed the opinion, that bees kept in the cellar through the winter are more tender in the spring than those left out all winter. Be that as it may, I think I would rather have them out all winter than to take them out of the cellar in February, in this locality. As to taking them out for a fly in winter, and putting them back in the cellar again, I do not know; but I rather think I would take the chance of their staying. In the winter of 1885-'6, some colonies became afflicted with diarrhea, and began to spot the fronts of their hives. I suspected they had been too cold, as the fires had been rather low. I then raised the temperature of the cellar, and the disease made no further progress. This is the only instance of the kind I ever experienced, and there is a possibility of some mistake; but if I ever see diarrhea in the cellar again I shall try better fires. If I had no stoves in my cellar I think I should try hot stones, jugs of hot water corked tight, or something of the kind. Of course, I should not use hot coals or any thing that would make any steam, smoke, or gas, or any thing that would make the air less pure.

Of late years I have taken the blooming of the soft maple as indicating the proper time to take out bees. Please bear in mind, that what may be all right in one climate or locality may be all wrong in another. Well, the maples have helped to keep me straight. Sometimes a bright warm day comes, and I want, oh so much! to see the bees all out flying; but if the soft maples are not yet out, I manage to hold on, and generally find it would have been a bad job if I had yielded to the temptation to take them out earlier. On two separate occasions I think the soft maples made a mistake in opening out too early. One year they started out in bloom, and

then some cold weather came, froze up the blossoms, and I think little or no nectar was obtained from them. In the spring of 1886 I felt especially anxious to get my bees out early. Sickness and death had prevented their getting the attention they should have had the previous fall, and some were short of stores. Just which they were I did not know, and I thought if I overhauled them in the cellar to find out which needed feeding I might injure the great majority which needed no feeding, and so make more loss than gain. So I watched the maples closely, and on March 26 found one putting forth blossoms. It was unusually early, and it did not look like settled warm weather; but there were the maple-blossoms, and I didn't want any bees to starve in the cellar, so out they came. If I remember rightly there were about 12 dead out of the 340 put in in the fall. A snowstorm came and for days they were frozen in. Then a bright sun, and, for all of my shading the entrances, many were lost in the snow. By the time they all got through dying off, only 226 were left, and they were by no means in fine shape. This occurrence is entirely too recent for me to feel any great pride in relating it, but the relation may do some good. The bees were in good condition in the cellar; and if I had it to do over again I would let them take their chance of starving, for at most I do not think many would have starved; and if left in the cellar till warm weather, I think many more would have pulled through all right. So I shall no longer put implicit trust in soft maples—at any rate, not in the blooming of a single tree, but take somewhat into account the date and general appearance of the weather. Although this one tree was in bloom March 26, it was many days before the general blooming of soft maples; and if I had waited for this they might have been all right. Since 1872 my bees have left the cellar at the following dates:

1873, March 31.	1880, March 31.
1874, " 30.	1881, April 22.
1875, April 6.	1882, March 30.
1876, " 17.	1883, April 6.
1877, " 11.	1884, March 29.
1878, March 12.	1885, April 8.
1879, April 1.	1886, March 26.

As I have already intimated, some of these dates would have been better if later.

Marengo, Ill., Mar. 2, 1887.

C. C. MILLER.

I think you are right, friend M., in deciding that too late is better than too early in putting the bees outdoors. Almost every bee-keeper, especially an enthusiastic one, is anxious to get things going in the spring, and one has to live until he is forty or fifty years of age before he learns that the weather in March and April is very uncertain. I have gone through the same experience in risking plants out over night; but I think I have never regretted that I protected them too well. Our bees are, however, always prepared for outdoor wintering, and therefore are outdoors all winter long; but I have to check the boys continually about taking off the chaff cushions too early. They complain that it is too much fuss and bother every time they wish to open a hive; but my impression is, that it pays a good per cent to have them well protected when these sudden cold storms take us unawares.

THE HOME OF THE HONEY-BEES FOR 1887.

A GLIMPSE INSIDE AT THE WORKERS.

FROM time to time we have given our friends notice of the improvements we have been making. We have recently, as you know, erected another brick building, 96x44, two stories and a basement, to accommodate the increase of business. We presume all the readers of GLEANINGS will be pleased to take a view of the Home of the Honey-Bees, where from 15,000 to 20,000 hives, and millions of sections, are made and shipped annually.

That you may get a better view of the place where the busy workers are laboring in the interest of apiculture, we will get off a little way on an elevated spot and look down upon the Home of the Honey-Bees, of which the floor room aggregates an acre or more. Our view, then, is as seen on the next page. That we might have a good view of the surroundings, we told our engravers to spare neither pains nor expense in the execution of the picture, and our readers are to judge for themselves. During our busy season things look very much as in the engraving. There is, in the left, a new freight depot where all our freight is put, ready to be placed on the cars. This building was erected by the railroad company largely because the increase of our business demanded it. We also load heavy shipments directly on to box cars run down on our side-track, right about where the locomotive is standing. It is just pulling out some flat cars which had been loaded with lumber for hives. The main building in the foreground you will recognize as the main factory that we have previously shown our readers. The structure just below is our new building. There all our sections, crates, hives, etc., are cut out by automatic machinery, and there, too, all our tinwork is done. Just over the main building you see our barn and the top of the house apiary, the former shown on page 984, GLEANINGS for Dec. 15, 1886.

We will suppose, dear reader, that you have come for the purpose of making the Home of the Honey-Bees a visit. You know that our bee-friends are always welcome, and, entering the main building, you pass up the stairway into the main office. We will suppose that you have come, fortunately, just when we have a little leisure. After a little preliminary we begin by describing the room we first find ourselves in, which is our office, 40x60, where all our correspondence is conducted. Here are from twelve to fifteen clerks at work, busily writing. Yonder is the book-keeping department, where two or three ladies are constantly at work on accounts. One of them has the large index-book that contains the names of over 20,000 different people with whom we have had deal. This book alone cost over \$75.00. With so many names, do you wonder that once in a great while our girls get the same man on two different pages—that is, they have two accounts with the same person, without knowing it? The consequence is, he may get a statement, say-

ing there is so much *due him*; and then a few days later on, another to the effect that he is *owing us*; and this time he gets mad; and when the girls get a "blowing-up" they hunt the matter up and find where the trouble is.

At the right of the book-keeper is the lady who opens the letters and counts the cash. This is one of the most important posts in our business, for it requires some one who can so apply the mind to the work that nothing that is going on can draw away the least attention. When somebody says he put so much money in a letter, and the clerk who opens the mail declares there was a different amount, or no money at all, there is a chance for a quarrel, I tell you. Now, if you will stop a moment I think I can explain to you right here why the friend who sends the money is much more liable to be mistaken than the clerk who opens the letters. Now, if you don't wait until I explain, you will be inclined to say that one is just as liable to be mistaken as the other, but you are wrong. See here: Right under her hand is a little drawer. In this drawer is a printed postal card. This postal card reads, "My friend, your letter, saying, 'Inclosed find 75 cts.,' is now in my hands, and there is positively only 25 cts. in it instead of 75. Both the letter and the envelope are now in my hands while I write this card, and there is no possibility of a mistake."

The card does not read *exactly* like the above, but it is the same in effect. If I am present, the clerk often calls me to witness that there is no more money, no postage-stamps, and nothing inside of the envelope, or stuck on the other side of the letter, or dropped out on the desk. The desk is a large one, arranged expressly to avoid the possibility of any thing being dropped; and the clerk who presides makes it her every-day business to watch over every copper with the utmost care. In fact, she has nothing to do but to look after this one thing that often makes so much hard feeling. Most of the time, it is true, the friend who receives the card writes back, saying that he trusted it to his wife or neighbor, or somebody else, and they put in the 25 cents in stamps, and brought back the 75 cents in change, instead of doing the reverse, or something of that sort. At other times the friend who sent the money declares positively there was no such thing as a mistake on his part, and we have to settle it as best we can.

We must get along, however; for if we stop to talk about the other clerks' work as we have this one, it will take a good while.

There is GLEANINGS desk; here, the mailing-desk; there, a stenographer's desk; and just back of him is the letter-press. There, again, is another stenographer. By the way, we have now three shorthand writers, with two type-writers and one caligraph, and the whole are kept pretty busy, I tell you, and even then some of our friends feel hard because our answers are so brief and unsatisfactory. I assure you it is a pleasure, though, to be able to have every word you say in answer written down, especially when you have had experience by being overburdened with business correspondence. Here is a

queen-desk, and over in the corner is the express-desk. You see, dear friends, we are doing all we can to answer all your correspondence, and to attend to all necessary business with you. Every thing is arranged in departments, and every thing works systematically. Each clerk has her particular duties and her special instructions.

We will now pass into the paper-room, where from six to a dozen girls are at work folding the papers and binding the A B C book. From this room we pass into the paper-cutter room, where GLEANINGS and all our A B C books are trimmed. We next enter a long hall where the names of all our subscribers are standing in type. Passing out the east end we come into the general job and composing room; going further, and turning to the right, we enter another room also a composing-room. At the end of said room is still another stenographer (our proof-reader) working busily at his post. He is no other than W. P. Root, with whom our friends are now perhaps partially acquainted.

We will next enter the sample-room, where samples of nearly all our apian supplies are kept in stock. After looking over the various implements, and explaining their use to our bee-friends, we next enter the smoker-room, in which from 10,000 to 18,000 smokers are put together annually. There are other rooms on this floor, but we will not stop to go through them. We pass down the stairway, and enter one of our large packing-rooms which is 70x40 ft., and formerly was the old saw-room. Here a large portion of the goods are packed, ready for shipment, by experienced men. We next pass into another packing-room, where we find Bert, "the clerk who never makes a mistake," marking off goods for a customer. The boxes and packages are stacked one upon the other, and it is almost impossible for us to get through. Near this is the express-room, in which all the goods are put up that go by express. We next enter the press-room, where GLEANINGS, our price list, and the A B C book are printed. The press is one of the best Cottrell & Babcock makes. It not only runs nearly every day in the year, but sometimes all night; and the number of impressions it makes annually, aggregate about 3,000,000.

We will retrace our steps, edge around the boxes, and pass down into the machine-room. The first thing that greets our ears is the perforating machine which "chanks, chanks" at the shining sheets of zinc. Here is an iron-planer and three or four lathes. In this room our repairing is done, the making of mandrels and comb-foundation mills, besides other iron work connected with the apian-supply business. Let us stop a moment and look at the comb-mills which are in process of manufacture. The man with the glasses stands watching the machine, with a lever in each hand, while the cog-wheels and knives obey his will. We can not stop longer. We enter the boiler-room where all the steam is supplied for all heating purposes, and for propelling the machinery. There are two automatic feed-pipes for conducting the sawdust, shavings,

and sticks directly from the wood-working machinery into the boiler-furnace; and all that is necessary for the fireman to do is to shovel in coal. While running the two planers or the cutter-heads, the boiler is nearly self-feeding.

We now open the door, and pass back again into the machine-room. The first thing that confronts us is our deep well-pump, 96 feet deep, supplying all the water necessary for propelling the machinery, and heating. We pass into the wax-room, where are from 10 to 15 girls and young men busily at work making foundation. Here is a couple of dipping-tanks, from which three or four girls are dipping wax into long sheets. At our left are two or three comb-mills running out the thin foundation. At our right are two machines running out heavy foundation. The two latter are propelled by steam. The girls complained last year about its being hard to turn the rolls by hand; but now we have called our big engine to assist; and I tell you, friends, it is a great help indeed. At the end of the wax-room is a man making boxes, and boxing foundation.

We will now go through the underground passageway where we have our underground railway. Here you will find stacks and stacks of goods. We follow the track until we come to what was originally our old tin-room. This is now used exclusively for the storage of counter goods and seeds. We pass up the stairway, and, lo! we are in the counter store, pretty nearly back to where we started. Here you will find two or three ladies keeping the counters filled as packers and customers take away the goods. You exclaim, "How is it that you can furnish such nice-looking goods for such a small sum of money?" It does seem incredible, I know; but the secret is in knowing where to get goods at a low cost, and in large quantities. A man was in Saturday to look after the working of some of the new machinery his house had put in. He went into the counter store and picked up an adjustable wrench. Pretty soon he came to me, saying, "Mr. Root, what does it mean, that you sell a good-sized, well-made adjustable wrench like this for only 25 cts.? Do you really steal them?"

"Why, no, my friend, we don't steal them, but we do this: We write to some large factory, and say, 'Gentlemen, how low will you make us five gross of eight-inch wrenches, providing we will give the order away ahead, so you can make them at your leisure—during a dull spell, for instance?' They reply, that if they can take their own time, and make, say, a part of them at one time and a part at another, they will do so and so, and that is the way we get low prices on many things." But, to return.

Thus far we have just gone through only the main building. We will now retrace our steps and pass through the packing-rooms until we come out of the door seen just at the right of the locomotive going up the track. We pass along this elevated sidewalk and open a door at the end of the new building. Here we are greeted by the deafening roar of humming machinery. The

THE HOME OF THE HONEY-BEES IN 1887.

MURRAY & CO. N.Y.

first machine that we see is the automatic section-machine; and at every zip, zip, zip, a section drops down and is picked up by a boy who packs them in the boxes. There are about 20 machines in this room, but we will not go into details, as we propose ere long to give our readers a picture of it. We now pass upstairs and enter the tin room, 44 x 96. Here we are greeted by the din of tinner's mallets. Here are two men working at the insides of extractors. Further along, the cans are being made. There is a pile of wax-extractors, comb buckets, honey-pails, and all sorts of tin honey-receptacles in process of manufacture. We retrace our steps, and pass down into the basement. Here is a great amount of belting and shafting, all in full motion. There is a 52-in. exhaust-fan, which is connected with large pipes. These pipes are connected with smaller ones communicating with the different saw-tables. This exhaust-fan, or blower, carries away all the shavings, sawdust, and little sticks, and blows them through a large main pipe, and from this building (through a pipe as seen between the two buildings just below the locomotive smoke) directly into the shaving-vault. The sawdust is then conducted by means of another pipe directly into the boiler-furnace, which we have before described. Now, right opposite the exhaust-fan is the blower for blowing cold air through a coil of steam-pipes. The cold air is thus heated and carried right up into the saw-room and tin-room, thus giving the men an abundance of fresh air.

We pass from this shaft-room directly into the engine-room. You will exclaim, "That is such a little thing to do such a large amount of work!" I reply, "The engine looks small, but it represents 90 horsepower!" After looking at the engine, we pass through an underground passageway leading to the main building into our greenhouse.

There is lettuce, radish, pie-plant, celery-plants, etc., growing as if it were warm summer weather. Hark! what do we hear? It is the peep of young chickens. What are they for? Why, they are our bug-catchers. We know of nothing better to keep the bugs off the lettuce. Here we finish our trip through the buildings.

Now, friends, I do not know how it seems to you, but when I take a look at this scene of activity it seems to me almost as if it could not be reality. It was only a very short time ago that I was a blundering boy—yes, a boy who cried over his plans because they did not work just as he had figured out they ought to work. When this blundering boy, however, stopped working for himself, and began working for the kingdom of God, and his glory, giving employment to those who seemed to be in sad need of it, etc., then, by some strange process, success seemed to crown his humble efforts. It seemed as if some great and mighty power had the control and management; and who shall say that such has not been the case while the little motto still remains, cut in the solid sandstone right over the arch, in the center of the main building—"In God we trust"?

OUR P. BENSON LETTER.

MOER BEEKEEPIN AS A OCKYOUPASHEN.

IF beekeepin shood be confind to enny I class it hed ot be wimmen. No other calling in life is so suitful for beekeepin as wimmen. Thay air so genteel in thair moovments as to subdoo the moast vishus hybirds.

Next to wimmen is milliners and dress maikers, whitche is the moast appropri8 of all to keep bees, bekoz for the resaon thay can raise thair oan wax to wax the thred to so with. Also she kan so onto a bunnit while watchin for swarms.

BEE-KEEPIN AS A OCKYOUPASHEN FOR MILLYNERS.

A miller is espeshelly sooted to keep bees, bekoz he ken maik his oan flour and meel to feed the bees, and save them the trubbel of going out to gether poland off the blossums.

A carpenter hed ot to keep bees moar than enny-buddy els in the hoal wirl. It woont cost him nuthin for makin hives.

A still moar proper pirsion to keep bees is a mar-rid man or wooman. Thay have plenty of children to eet the hunny.

In no way is enny I in sitch good condishen to keep bees as a old batcheller or a old maid. Thay hev no children around in the way to be took care of when thay want to taik up a skep of bees and get the hunny from them. Then too its a good plan for them to get a good start in beekeepin, for if thay shood ever git married, it woud be reel handy to hev the children a round when the bees swarm, to yell & holler and pound on tin pans.

No class of people ken so well keep bees as conducters, brakemen and sitch, onto a ralerode. Thay need sum employment to taik up thair spair time whitche doant require enny at10shun, and bees talks cair of thairselves, and doant need enny work. Besides if he bies a swarm of bees he ken taik it home on the baggige car for nuthing.

Lawyers is pre-emant for keepin bees. When bizness is kinda dull bees helps to maik things lively, and he ken put a swarm clost up to the side-work soze to sting people agoin along and from whitche he ken eezy git up a lawsoot to maik him bizzness.

A irishman is the proper pirsion to keep bees for his pipe is always a goin and reddey to smोक the bees.

A woshierwooman is also the right I, for she ken rays her own beeswax to greeze her flat ierns to iern shurts.

The yung is good to keep bees, for thay kan lurn habbits of gittin around lively, and the oald is good for thay ken learn to cluster quiet at the door a doin nothin.

Hents it is seen that all classes and condishens hed ot to keep bees without regard to race, kuller, or prevus kondishen of servitood.

P. BENSON, A. B. S.

TEN-CENT SECTIONS OF HONEY.

A PROTEST AGAINST THEM.

FRIEND NOVICE:—I wish to raise my voice in an humble but earnest protest against the new departure. There is already an evil in this line which works more mischief than you imagine. It is this catering to the demands of the dishonest grocer who wishes to sell 12 oz. for a pound, either that he may get more profit or that he may appear to undersell his honest neighbor. The closer the bee-keeper sticks to the fundamental truth, that it takes 16 oz. to make a pound, the more successful will he be in increasing the sales of honey, and in laying a sure foundation for a steady demand in the years to come. Two conditions are wanting to make the ten-cent comb a success. One is, that all honey be of equal value; and the other, that all bee-keepers and dealers be strictly honest. To the honest bee-keeper I can see only evil in this, the limit being in the wrong direction. The grocer must get a certain number of combs for a certain sum of money, which puts a limit to the price of the finest grades of honey which the bee-keeper produces. In the other direction there is no limit, the greedy or dishonest grocer demanding more and more ten-cent combs for a given sum of money, and the producer tries to please him by giving as much surface as possible; and if he be of the same spirit as the dealer, he puts in all the wood he possibly can. The tendency all is to give as little honey as possible for the ten cents; and I fear that, in two or three years, ten-cent combs of honey can be found so small that the gentleman of Albany could "clean up the platter" at one meal, without the help of the family. Notice, friend Novice, he suggests 10 or 11 oz., while you suggest 8 or 9. Some one else will suggest 5 or 6. Where is the limit? When you make a package of comb honey less than a pound, I think you simply increase the cost to no purpose. Where a pound of comb honey can be retailed for 16 or 18 cts., or even 20, there is no need of a smaller package. Did you figure up how much the bee-keepers who sent ten-cent combs to Albany received per pound for their honey? Allowing that 100 lbs. net would make 150 combs, say the grocer pays 8 cts., making \$12.00; deduct commission, 60 cts.; expressage and drayage, not less than 75 cts.; cost of 150 frames and case, 60 cts., leaving a balance of \$10.05 for 100 lbs. net of honey—just about equal to getting 9½ cts. for 1-lb. sections, weighing the frame with the honey. Is not this making undue haste to reduce the price?

Wouldn't it be better to go slow in this matter, and treat the story as a huge joke (which was probably intended only as such), that one man, without any special effort, sold, in a little over half a season, in the city of Albany, nearly if not quite a quarter of a million, or between 60 and 80 tons, of a size of comb which seemed to be new, to a convention of York-State bee-men? And before you settle the matter, ask for the opinion of some of the bee-men who sent the quarter of a million of ten-cent combs to Albany during the past six months. In the one-pound sections which you send out, the frame is so light that the consumer does not object to having the frame weighed with the honey; but having the idea firmly implanted in their minds that honey should be sold by weight, they do demand, as they have a right to demand, that when they pay for a

pound that at least the honey and the frame weigh a full pound.

During this winter I have sold several tons of California honey in the comb to the best grocers of this city and Pittsburgh; and although the combs average nearly 2 lbs. each, it sells readily. Two things they do require: That the quality be good, and that the comb and frame weigh all they pay for. I do not mean that there is no preference given to the 1-lb. section; for my experience is, that the one-pound package does command in this market just about one cent per pound more than the same grade of honey in a 2-lb. package. When you collectively, as bee-keepers, have the power to say how many ounces the ten-cent comb shall weigh (net weight of honey), and can compel every producer to live up to your law, then, I say, go ahead with the ten-cent comb; but this being the freest country in the civilized world for the man who wishes to defraud his neighbor in weights and measures, you will find neither profit nor satisfaction in the novelty proposed. The class who buy for every meal something to spread on their bread, and who demand a ten-cent comb, is the class whose trade you can never get to any extent unless you are prepared to compete in price with the manufacturers of truck which they call jelly, and which can be retailed at 5 or 6 cts. per lb. M. H. TWEEDE.

Allegheny City, Pa., Feb. 24, 1887.

Friend T., you have presented an excellent paper on this side, stating the objections to the ten-cent package, but I think you have overlooked one or two points. The reason why I proposed 8 or 9 ounces instead of 10 or 11, is because the 10 or 11 ounces were *buckwheat* honey. This, you know, makes quite a difference. I admit, however, that there is some difficulty in regard to the matter of quality. One producer might bring in a lot of very choice ten-cent sections, while his slipshod neighbor would have a similar lot that might have to be sold for 5 cents to close them out. For all this, I do think the ten-cent package would sell, a great many times, where any thing costing more money would not. Your article has suggested that we might, in sorting our 1-lb. sections, pick out, by weighing, certain ones that could be retailed for a dime, and crate these by themselves. In our trade we find quite a good many that do not weigh much more than 10 or 12 ounces. Mark these, "*Your Choice for 10 cts.*," and they might go off quite readily. I did not understand, while at Albany, that any one contemplated short weights at all: it was only to arrange a plan whereby sections might be sold at so much, and thus avoid the necessity of weighing. Some one asked the question of Mr. Wright, how he would prevent consumers from picking out the most desirable sections first. He replied, that there was no remedy. Of course, the grocer would put only one case on the counter at a time, and insist on selling every section before opening another one. He said this same thing happens in all kinds of produce. The last potatoes in a barrel will be the poorest, and so with most kinds of vegetables; but the last purchaser must take what is left, for no dealer could afford to open a new package of choice specimens while the half-broken package remained un-

sold. Weighing up every section sold, and giving full 16 oz. to the pound, is surely the fairest way; but it is a laborious operation, and where only a penny, or even a couple of pennies, cover the amount at stake, it seems as if there might be some speedier way, by lumping off the goods, as it were, instead of going through with the slow process of figuring by ounces. I am sure there is such a thing as wasting more time over pennies than they are worth—in some kinds of business.

THE SCIENCE OF MAKING HONEY VINEGAR.

HOW TO MAKE IT ON A LARGE SCALE.

ON page 64 of GLEANINGS, Jan. 15, E. France tells how to make vinegar from honey. This way will do very well on a small scale; but to make a larger quantity of vinegar, or for the manufacture of it, we need a quicker process. Two years is too long a time for the manufacturer to get his money back for the honey he bought.

To get vinegar, the honey-water has to undergo two different changes: First, the sugar is changed to alcohol and then the alcohol is changed to vinegar—an acid. The latter process is done by growing small vegetables on the surface of the alcohol holding water. By this process there is needed a sufficient amount of air. It is a good plan to separate these two different processes by manufacturing the vinegar.

About the sweetness of the honey-water, it is different for more or less strong vinegar. Thus, if you wish 5 per cent acid in the vinegar you can make the honey-water holding 10 per cent of sugar; or you take 20 per cent of sugar and mix later with one-half of water. So the honey-water can be made holding 8 to 20 per cent of sugar, corresponding with 4 to 10 per cent of acid in the vinegar, nearly. More than 20 per cent of sugar will take too long a time for fermentation, and for changing alcohol to vinegar, or this process would be impossible. For this we want to know how large a per cent of sugar is in the honey-water. It is best to use, for this purpose, an areometer—the same as is used in making wine or beer. This is far more exact than the floating egg, which corresponds to 15 or 18 per cent of sugar, and this gives a strong vinegar.

The honey-water is now put in a standing barrel, with one head out, and here it commences to ferment pretty soon. The higher the temperature, the quicker the fermentation. After about 9 or 10 days, the areometer will show you only 2 or 4 per cent of sugar, and now we will call the honey-water honey-wine. This honey-wine is filtered in barrels till it is clear. The oftener it is filtered from one barrel into another, the quicker it will be done. It will help very much if some fruits of any kind are given with the honey-water in the standing barrel. This will give some tannin to the honey-wine. This fruit can be used a second or third time; so will a small quantity of common cream tartar quicken the process. In about two or three months the wine will be clear enough.

To change this wine to vinegar we know several different ways. I will explain only two.

1. To make vinegar in small quantities, take

some tight barrels, and pour into every one 15 gallons of good old vinegar and 15 gallons of the honey-wine, above described. In about 4 weeks (with high temperature in summer) you can take out of every barrel 15 gallons of vinegar. Now fill up again with 15 gallons of honey-wine. The barrels are about two-thirds full this way, and have to be open all the time. So every barrel gives 15 gallons every month.

2. For a larger quantity of vinegar I approve the following method:

Take any flat vessel, put in some ferment of your honey-wine, and some water and vinegar. In 14 days or 3 weeks you will have on the surface of this water a large quantity of vinegar vegetables, and you will need this for the following process:

The honey-wine, mixed with one-fourth or one-third of old vinegar, is put in another standing barrel, and the above-described vegetable is planted on the surface by a thin well-wetted board. The vegetable will grow, by high temperature, very quickly. In 18 hours the whole surface will be covered by it. In nine or ten days the alcohol is changed to vinegar acid, and the vinegar vegetable falls down to the bottom. The vinegar is now filled up in barrels, and sold. The standing barrel is cleaned, and filled again with the so-called honey-wine. By pouring the vinegar into barrels it is a good plan to mix it with a small quantity of honey-wine; the vinegar will keep better and stronger. The barrels should be well closed. By this method the honey is changed in 80 or 100 days to the best vinegar.

If the honey cost about 5 cents per lb., this vinegar will be cheaper than good wine vinegar can be made; but vinegar made of corn and grain can be sold at a lower price, for the starch and sugar which are to be converted into vinegar will cost not more than 3 cts. per lb. But the honey-vinegar is far the better, and nearly as good as the best wine vinegar. Spirituous vinegar can not be made in the United States, on account of the governmental dues.

Let me give some more rules for its manufacture. On an average, the honey will contain about 75 per cent of sugar. By making the honey-wine, about 15 per cent of the fluid is lost, and in vinegar-making, not quite 10 per cent. The higher the temperature, the quicker the process, but the greater the loss.

All this I have verified by many experiments, and it seems to me not impossible to manufacture the honey-vinegar on a large scale.

Selma, Tex., Jan. 27, 1887. L. STACHELHAUSEN.

I will explain to our readers, that friend S. would probably prefer to write the above letter in his native German than in English; yet the facts he furnishes are so important we give the article, as nearly as we can, as it came from his pen. There is something wonderfully interesting to me about this vinegar-plant—a plant that will cover the surface of a barrel in only 18 hours. And this reminds me of a vinegar-plant which was propagated and sold, perhaps 20 years ago. It looked like a piece of loose cotton, or, perhaps, like white vinegar-mother. Well, if a little bunch of plant was placed in a glass or jar of sweetened water, and the whole placed in the sun, in a warm temperature, that plant commenced growing by

taking the sugar from the water, and converting it into vinegar. Unless the plant was kept supplied with sweetened water, it died; but when well fed it grew enormously. The white flakes kept up a constant motion by alternately sinking to the bottom of the jar, and rising again. This motion was caused by little globules of gas that were constantly forming and enlarging inside the flakes of mother. When they rose to the surface the gas passed out into the air, and made the flakes drop again. I wonder if any of the readers of GLEANINGS know where this plant can be obtained. Years ago, while in Boston, I saw a man on the street-corner, selling a summer drink manufactured by the same or a similar plant. While it was foaming from the rapid growth of this strange plant, in the warm sunshine, it was poured into goblets, iced like lemonade, and served to customers.

HOUSE-WARMING.

W. F. CLARKE ON SLEEPING IN COLD BEDROOMS.

I WANT to back up what Prof. Cook says about making home comfortable in the winter time, regardless of cost. There are some economies that are "penny wise, but pound foolish."

To save a few dollars at the expense of the comfort and health of a whole family is surely a great piece of folly. Yet it is what many people are doing every winter of their lives, and I think this is especially the case with the farming community. According to my observations, there are few country homes that are really comfortable in the winter time. In most farm-houses an ample kitchen forms the living-room. There the meals are taken, and there in the evening the domestic circle is formed. Few country houses have more than one fire constantly going. This warms the living-room, and perhaps one bedroom which opens out of it. The rest of the house is cold most of the time. There is, very likely, a sitting-room or parlor; but a fire is kindled there only on "high-days and holidays," on Sundays, on wedding or funeral occasions, and when there is company. There are exceptions to this. In some farm-houses there is a hall stove kept going. In others, a fire is constantly burning in the parlor or sitting-room. But from my travels and observations, I am inclined to think these cases are largely in the minority.

In this country many of the better class of farm-houses are built of stone. This material makes a most substantial and durable building, but it is one that is extremely cold in winter, unless artificial heat is applied. A stone wall becomes permeated with dampness, absorbing moisture from the earth by means of capillary attraction. Flesh and blood are more sensitive to damp cold than to dry cold. A frame house, being to a great extent porous, admits both cold and heat more freely than a stone house. In a severe spell of weather, cold gets into a stone house and stays there, while a frame house becomes perceptibly warmer when the temperature moderates out of doors. Brick houses are open to the same objection as stone ones, though in a lesser degree, unless they are built on the hollow-wall principle, as few brick houses are.

I stopped over in a stone farm-house one night in Nov., 1885. The spare bed was very nicely fixed up,

even to "pillow-shams." There was a pile of bed-clothes, and the sheets were woolen ones. The bed was soft, I was tired, and every thing seemed to invite repose. But I could not get warm all night, though I kept on my flannel shirt and drawers. In the middle of the night I shook as with an ague-chill. Already, though winter had scarcely begun, the damp cold had gained foot-hold in that room, and the heat of my body was insufficient to overcome the chilliness garrisoned in a big heap of bed-clothes. Next day, some conversation sprang up about warming bedrooms in winter. Of course, I did not complain of my quarters; but in an "aside," some of the young folks told me "pa" and "ma" had no idea how cold it was upstairs in winter:

The trouble of it is, too many of us are all the time getting ready to live. We look forward to a future of enjoyment when we shall have made some money, and prospered sufficiently to have all things pleasant about us. Meantime we pinch and punish ourselves and those dependent on us, and wait indefinitely for "a good time coming," which is very long in arriving, and perhaps does not come at all. The poet Young says:—

"Of all man's ruinous mistakes, this bears the palm:
That all men are *about to live*,
For ever on the brink of being born."

Meantime, the years are gliding by. Age is creeping upon us. Our children are leaving the homestead, and setting up for themselves, carrying away with them the recollection of summers passed in hard outdoor labor, and winters that have been cold and dreary work in the barnyard or kitchen during the day, a brief "cuddle" around the cooking-stove after supper, and then ascent to a cheerless, chilly bedroom, where, after many preliminary shivers, forgetfulness of all trouble and discomfort is found in sleep. Is it not desirable to put a little more enjoyment and brightness into our own and our children's lives? Why must we be like Aunt Nabby Powers, who was constantly ejaculating, "Lame! Enjoyment here below ain't for me. I'm one o' them that's of few days and full o' trouble; as the good Book says, 'It's a world of tribbylation,' anyhow. Lame! lame!" We hang up "Home, Sweet Home," on our walls; but do we translate the motto into every-day experience as we might, could, and should? I make all due allowance for the struggling and calculation necessary on the part of many families in the country as well as in the town; but I know some farmers whose land is clear, whose buildings are good, and who have money out at interest, who, from carrying the practice of economy too far, deprive themselves and their children of comforts that could well be afforded, and would make life far more worth the living.

This plea for house-warming has expanded to an extent that leaves but little chance for adverting to the professor's plea for furnaces. As already remarked, I agree with his views in the main, and go for the furnace method, with careful construction, in all cases in which the cost can be afforded, and the house is of some size; but a house no larger than that described by the professor can be warmed more cheaply than by means of a furnace. My own is of about the same dimensions, and is made as comfortable as need be as follows: A \$30.00 base-burner stove warms the sitting-room and parlor, which are connected with folding-doors. The pipe goes directly into a small hall, and takes the chill

off that. A small Franklin stove, lighted only in extremely cold weather, is in the parlor, always open for ventilating purposes. In the kitchen and living-room (combined in our house) is a most effective parlor cook-stove, fed by wood, the pipe passing directly upstairs, and warming two bedrooms quite sufficiently for sleeping purposes. There is a bedroom downstairs connected with both kitchen and sitting-room, and a spare bedroom upstairs, easily warmed by putting on a little extra fire in the base-burner and Franklin stove downstairs when there is company.

The objection to Prof. Cook's plan with many will be the first cost of the furnace, which will be from \$150 to \$200. To my mind, another great objection is not seeing the fire. A fire warms you up better, if you see it. We read in Scripture, "Aha! I am warm, I have seen the fire." If Prof. Cook will deduct enough from his \$40 fuel-bill for the furnace, to run an open wood-stove in his sitting-room, he will have a "fireside," and a "domestic hearth," which he hasn't now, and he will find the ventilation better. I advise him and all others wishing to get the most home comfort out of winter fires to send to the Smith & Anthony stove-makers, 52 Union Street, Boston, Mass., for a little pamphlet entitled, "Some artistic fireplaces." The professor was "brought up in the warmth and glare of the old fireplace." So was I; and there was cheerfulness and luxury as well as warmth about it. It is all very well not to have the pleasant living-room "cumbered with ugly stoves and coils," but you do not need to have an *ugly* stove. I have one that is "a thing of beauty and a joy for ever." When its two stories of mica windows are lighted up with anthracite radiance it is next only to the old-fashioned fireplace I was brought up by. And if I want to recall the vision of that I can start up the open Franklin. Let me say, there is no escape of hard-coal dust or gas from a properly made base-burner stove, and its draft is constantly carrying off the foul gases with the lower stratum of air. The care of such a stove is less than that of a furnace fed with wood.

I, too, get up first, and light the cooking-stove, as I presume the professor does; and then I usually stir the porridge, which I like well boiled. Then it is but the work of a few minutes to shake down the base-burner, put in a scuttleful of coal, turn on the dampers, and empty the ashes. All can be done so neatly, that even if Mrs. Professor wears magnifying-glasses she will detect no litter. Another shake-down in the evening, and a second scuttleful of coal, completes the care of a stove "worth its weight in gold," if I couldn't get another like it for \$50. I am sure this is far less work than the care and attention needed by a wood-furnace. If I ran a furnace, it would be a coal one. Boynton's, and others that might be named, are as clean and sweet as furnaces for wood.

W. F. CLARKE.

Guelph, Ont., Feb. 21, 1887.

I am very glad indeed, friend C., to have you take up this matter of making our homes pleasantly warm. When reading your article I remembered the time when I used to teach school and "board around." It is not pleasant to the women-folks, neither is it pleasant to the men-folks or children, to be around the cooking-stove in the way, and I think it will pay in dollars and cents for every household to have some sort of a pleasant room away from the cooking-

stove, especially where there are children in the home. A young couple, just married, can stand it very well around the cooking-stove, for they would be happy almost anywhere.

A VISIT TO AN APIARY AMONG THE GREEN MOUNTAINS.

NELLIE LINSWICK TELLS US MORE ABOUT THE "KNOW-IT-ALL BEE-KEEPERS."

THE middle of July found me in one of the loveliest valleys of the Green Mountains. In company with my friends I took long walks and drives, now following the valley road that crossed and recrossed a narrow, busy stream, and now climbing the steep mountain-sides. Sometimes I was delighted by seeing the bright flowers of a familiar home honey-plant, the willow herb, known to my friends by the far prettier name of Indian wickopee.

One evening at the tea-table Mary looked across at her husband, saying, "Can you tell me, Charley, why, above all other things, we have not thought to exhibit our village bee-keeper?"

"He shall be exhibited this evening at once," said Charley, promptly, pushing back his chair; and five minutes later we were walking down the village street.

We found our bee-keeper, his day's work done, smoking the pipe of peace as he sat beneath his own vine and fig-tree. When Charley introduced me and made known our wishes, the pipe mysteriously disappeared, and a friendly smile brightened his face, as, requesting us to follow, he led us down the garden paths to where a dozen venerable apple-trees spread their protecting branches over seventy-five colonies. It was a pleasant sight; and very pleasant to hear was the familiar evening sound, always reminding me of the wind in a pine-forest.

The hives were double-storied, run entirely for extracted honey; and in reply to a question regarding the size of the frame used, a cover was lifted. It was a flat cover, and the frames were so near the top of the hive that the excitable hybrids boiled over the edges on every side. I scarcely glanced at the frames, so possessed was I with the thought that I had caused him trouble by making it necessary to light a smoker, when suddenly the cover was pushed carelessly back into its place, crushing and maiming beneath its cruel weight a hundred innocent lives. An involuntary cry of horror passed my lips. Our friend looked up in alarm; but instantly divining the reason of my cry he smilingly said, "I conclude you have not kept bees very long if that hurts you. Now, we old bee-keepers don't mind such things, and we haven't the time to bother with smoke, or shoving a cover on so slowly as not to kill them."

Heaven forbid, thought I, that I should keep bees till I become so hardened!

Against one of the trees stood a swarmer—two long pieces of wood fastened together with pins, and surmounted by a light box. The strips of wood could be slipped by each other, and the pins inserted in new places, thus lengthening or shortening the device. But it was too heavy for a woman's hands, admirable though it might be for this strong, broad-shouldered man.

In one corner stood a small building in which he wintered his bees; and, throwing open the door, he explained that the walls were double, and packed with sawdust, and the floor deeply strewn with the same. At this time, however, the floor was covered with a matting of dead bees, and the close, unpleasant air, made it unadvisable to step within. Probably in the fall every thing was made sweet and clean before the bees were packed away, but I could not but think that our way of outdoor wintering, where the bees are sure to get pure fresh air, is preferable.

"Outdoor wintering," said our friend, "would not do for this location. Our winters are too severe."

"The severity of the winter," I returned, "would make no difference if the bees were properly protected."

"But the depth of the snow—they would be smothered," he insisted.

"We are careful, after every severe storm, to see that the entrances are free from snow." And then, stirred with a sudden remembrance of certain mistaken assertions regarding our winter management, I added, with some warmth, "and we never disturb our bees by rasping off the bottom-boards with a bent wire or piece of hoop-iron!"

"Ah! well," was the mild reply, "a way that pleases one may not please another;" and, dropping the subject of wintering, we passed on to the shop, with its medley of hives, frames, extractor, and rows of kegs and bright tin pails. Here the inexhaustible subject of marketing honey was touched upon, and this Vermont bee-keeper won my profound respect by assuring me that disposing of his honey was the simplest part of his business. Of two bee-keepers, the one finding a ready sale for his comb honey because of its beauty and the care he bestows upon it, and the other building up a reliable market for his extracted honey, the latter, in my opinion, deserves by far the greater credit.

As we were leaving, I asked if he would lend me a few bee-journals for a day or two, it had been so long since I had seen one.

"I should be glad to oblige you," was the reply, "but I am not taking any. A few years ago I did take Root's journal for a short time, but I soon found out that it couldn't teach me any thing. We old bee-keepers," he continued, with a quiet smile, "when we have once thoroughly learned our lesson, don't need the advice of bee-journals."

As we passed out the gate, admiring, Mary whispered, "How wise he is!" And then, giving my arm a little squeeze, she added, "How glad I am that we thought to give you this pleasure!" And Charley, walking before with a little pail of clover honey swinging from his fingers, glanced back with a nod and smile. And, indeed, it had been a pleasure; though when our host had cordially urged that our visit be repeated at an earlier hour in the day, when hives could be opened and the complete workings of his apiary exhibited, I remembered the bees he had so unnecessarily sacrificed, and excused myself with thanks. And notwithstanding his assertion, I think too highly of the class to which I am proud to belong, to believe there are many, even among "we old bee-keepers," who have so little regard for the lives of those who toil in our behalf. NELLIE LINSWIK.

Dear friend Nellie, I am very, very glad

you, have put in this plea for humanity for our little workers. I know there are many bee-keepers who do cruelly crush and mangle the little fellows in the way you describe; but no amount of argument will ever convince me that it is the right thing for a Christian man in a Christian country to do; and I am very sure it does not pay, either, in dollars and cents. I have seen colonies become unmanageable by just such treatment, and I have wondered several times, when discussing these matters in regard to bees being a nuisance to the neighbors, whether it were not possible that the whole trouble originated in this kind of mismanagement. I hate to be bothered with a smoker, when I am in a hurry; but by means of the enamel sheet to be placed over the frames before the cover is shut down, I can almost invariably close the hive quickly, and without killing even one bee. Why didn't the man take his pipe along with him, if smoke he *must*, and drive the poor little chaps back with the fumes of tobacco? Much as I object to such a way of doing, I think it better than to kill the bees without scruple.

A FOOT-POWER BUZZ-SAW FOR ONLY 10 CENTS.

RIGGING UP A BUZZ-SAW TO BE RUN BY A SEWING-MACHINE WHEEL AND TREADLE.

A FEW days ago, at an auction sale I purchased a Wheeler & Wilson sewing-machine for ten cents. I am real proud of my purchase! Of course, the sewing attachments are "no good," but it has a good fly-wheel, treadle, and a 6 inch belt-wheel. Now, I want to know if one of those \$2.50 saw-mandrels, with a six-inch saw, could be made to do good work on this machine. I wanted a regular saw-table, engine, etc., but—when!

I used to work in your saw-room, but it seemed to me that those saws were just "sighing" for my fingers, and that the rolls on that big planer were just "groaning" for my thumbs. I "sighed" for the office or the compositors' room (am still sighing), and felt quite relieved to get in the wax-room. Since that I have learned *how to saw, and how to be happy in doing it.*

If I can't convert this machine into a foot-power saw, I know what I can do: I can put an emery-wheel on it, swing it on my back, and go over the country sharpening honey-knives, scissors, etc. May be it would be too heavy, though. Since I have thought over Mrs. Chaddock's experience as book-agent (I admire her ambition) I have decided not to take the machine around on my back. If I can't make a saw of it I will take the machinery out, and use the table for an aquarium stand.

Groesbeck, O., Jan. 8, 1887. WALTER S. POWDER.

Friend P., this matter has come up several times before. A balance-wheel and treadle is exactly what is wanted to propel a buzz-saw, but the machine is too light for any thing like heavy work. If the stuff you wish to cut is only $\frac{1}{4}$ inch, possibly $\frac{3}{8}$, or even $\frac{1}{2}$, a saw made just right would do the work beautifully, very nicely, and true; but to cut stuff for bee-hives needs all the strength of a good strong man while standing on his

feet. Barnes' new foot-power saw-table has a good stout crank that can be used in place of the treadle; and I tell you, one stout man to turn the crank while somebody else does the sawing, does a great deal more work than where one has to tread, and feed the saw besides. For small fine work, for the use of pattern-makers, and some other artisans, your ten-cent foot-power might be a great convenience. I am glad you remember Mrs. Chaddock's experience.

SURPLUS-CASES.

MR. HEDDON GIVES US A CHAT IN REGARD TO THEM.

I WISH to have a little chat (over the caligraph) with you and your men in the shop, regarding surplus-cases. So far as I know, I was first to make surplus-section cases, which contained the bee-space at the top, so necessary to tiering up. If I was not prior in such invention, I was original in it, never having heard of any such thing, unless I have forgotten. I was opposed to separators at that time, and so I constructed what is well known as the Heddon case; and when you get your experimental apiary going, if you make experiments on a sufficiently large scale to tell the facts sought, you will find that this old case of mine is to-day the best ever made, and I believe the best that ever will be, where no separators are used. I believe it can not be improved. I shall not have time, in this, to give all the reasons. I wish I could be in your shop a little while. For the use of separators, I think the tin T case is preferable to it; and as I now desire to use separators, I wish to talk to you about the T case, which is no further a copy of my old case than that it uses the bee-space, and so can be tiered, which plan you will recollect I used to advocate strongly, almost alone, at one time.

I consider the tin T as radically an invention, and a good one too. I think it the coming case, for those who will use separators, and never care to invert them. I do not know who invented it, but I think I recollect seeing it illustrated in a back number of your paper or the *A. B. J.* Several years ago Mr. Vandervort visited me, and he told me that he used no other style of case, and fully explained to me all about how he made the T's and how he fastened them to the cases, and how he used a "follower" that pressed the sections by virtue of a spring. I found Mr. V. a man of far more than ordinary inventive ability, and a very fine mechanic, in both iron and wood. I do not remember whether or not he said he invented the T. As regards using them on the removable or adjusting plan, I also well remember seeing that explained in a back number of one of our journals, and I presume Dr. Miller can tell where. Any way, as soon as it gets to attracting any attention the owner will appear, for I feel sure that the rightful owner will claim a good thing, when we see that, if a thing is *very* good, men will claim it who never dreamed of it.

Two years ago we made some of these T cases, and of 5-16 sides, as you advocate. Years before that, we made cases just like Eaton's, illustrated on page 131, except the movable side, which we had

tested previously, and do not think can be made in any manner so as not to ruin the case. Mr. Eaton speaks of this case doing away with the honey-board, but it never will, because it can not be made to "break joints" with the frames below, unless too narrow sections are used. Besides, when he goes to tiering he lifts with his first case a whole lot of dauby brace-combs, to be placed above and attached at once to his new clean sections. But, why go further? Mr. Eaton is plainly no inventor, as other points in his case clearly show.

I would not make the L-shaped tin to support the T's, but tack a plain flat strip on the bottom edge of the side piece of the case, that would project inward enough to suit me. What can be better? and how much simpler! But I think you were right in the first place, in choosing the stationary rests for the T's. The reasons you give, together with the greater ease of adjusting the sections when they are stationary, to me, more than offsets all to be gained by having so many different lengths of sections in use in the same apiary, which is, in many other respects, a serious detriment. But here is the mechanical botchery of the movable T. The rest which holds it, must be so placed as to prevent the bees from entering the outside sections at their outsides, which, if they can not do, they will not so completely fill and so quickly finish, as when they can.

We give the following preferences to this T case: It is cheaper, and better adapted to the cheaper wood separators. It is also lighter. This is all.

The one-story wide-frame cases, as we now make them, we prefer for reasons as follows: With our screw method, we keep the frames tighter together; we can invert the sections or any longitudinal row of them, at will. We can "jump" these rows from outside to in, or vice versa, at will. The sections are always clean.

Dowagiac, Mich., Feb. 19, 1887. JAMES HEDDON.

Further on, in reply to Dr. Miller you will notice that we have discarded the L tins, and use instead short pieces of iron as recommended by friend Miller. You will see that this places the bee-space *above* the sections. You will observe, also, that we still make the T tins movable, for the reason that the majority of those using the T supers seem to prefer them that way. Many thanks for the suggestions you have made in regard to supers in general. This is a matter that is of considerable interest to us all just at this very time.

THE T SUPER.

ITS ADVANTAGES AND DISADVANTAGES CAREFULLY CONSIDERED.

FRIEND ROOT:—As the T super is now before us, a few words may not be out of place. I had 25 of these supers in use last summer; have been using them for two seasons. I

first got the idea from an article by C. H. Dibbern, in the *A. B. J.*, page 133, 1884. Mine are made for the old-style Heddon hive, but the principle is the same as you have described in *GLEANINGS*. Anyone is likely to see their advantages at once, and I will therefore omit them.

In simplifying the super, by using a continuous tin rest lengthwise at the bottom, instead of Dr. Miller's method of separate rests, you have gained

* I discard all "followers."

the advantage of being able to use other than the $4\frac{1}{4} \times 1\frac{1}{4}$ section by merely spacing the T's differently; but you have also incurred a grievous disadvantage. This rest closes the *outside* entrance to the *outside* sections. Now, you may at first think that this is not of much consequence; but if you do, you are mistaken. The trouble is not in the storing of honey, but in removing the bees when the cases are taken from the hives. If these entrances are left open—a *la* Miller—a few puffs of smoke, applied as soon as the cover is removed, will drive nearly all the bees down into the brood-chamber. If the super be now removed—before that inevitable reaction takes place, and the bees come boiling up again—there will not be enough bees left for a quorum; and if put in a tent or some other suitable place they will quickly adjourn. If, on the other hand, these entrances are closed, as you propose, the bees between the outside sections and the sides of the super can not readily make their escape, and it will be found impossible to drive them out. Now, if the super is placed in the tent, these remaining bees, because of their numbers, are by no means in a hurry to vacate. I doubt not that you will see the full force of this at once. An amateur would not be so likely to.

I have tried both fixed and movable tin T's. I much prefer the movable. They will space themselves more satisfactorily than I can space them. Besides, as you have said, they are better adapted for a follower.

Dr. Miller makes his T's out of two pieces of tin, 12×1 inch; mine are $12 \times \frac{3}{4}$ inch instead, and I have found them much stronger than necessary. This gives a $\frac{3}{8}$ -inch rest for the sections, and holds the separators $\frac{3}{8}$ inch from their bottoms. I think this preferable to $\frac{1}{2}$ inch. My T's are made of good heavy tin, however; perhaps you use lighter tin where they are made from one piece. The price of your T's is much less than I have been able to obtain the material ready to solder.

In the use of this super I have found one serious fault. Dr. Miller's supers are $17\frac{3}{8}$ inches long inside, while yours are $17\frac{1}{4}$. The sections occupy alone just 17 inches. This $\frac{3}{8}$ or $\frac{1}{4}$ of an inch is left for the tin T's, and a little room to work in. It is filled below, but not above. There remains this unoccupied space to be divided between the three spaces between the four rows of sections and the two spaces at the ends of the super. In the first place, if these spaces are not equal (and they are not likely to be) the sections are out of square. In the second place, a line of glue will be put along and down into each of these cracks. If a tin T be dropped down between the rows of sections above, to correspond with the one below, it will hold the sections square; but the last one will be by no means easy to insert, and a line of glue will be placed on each side where the two edges of the T meet the sections. Also, if we use separators $3\frac{1}{2}$ inches wide—and I want none narrower—a special T must be used above, or the T's must be made smaller than you are making them.

Lastly, if it is attempted to make the super short, and crowd the rows of sections together, it will be found difficult to place the last row (or, at least, the last few sections) in position, for they will strike on the tops of the tin T's.

I should like to hear Dr. Miller's experience on the glue question.

WM. DREW.

Iowa City, Iowa, Feb. 19, 1887.

THE T SUPER.

VALUABLE FACTS FROM C. C. MILLER IN REGARD TO ITS PROPER CONSTRUCTION.

FRIEND ROOT:—The L tins that you use in the T super have the advantage that they are simpler and more easily put on than the $1\frac{1}{8} \times 1$ pieces of sheet iron I use. They also admit of using sections $3.25 \times 4\frac{1}{4}$, $4\frac{1}{4} \times 4\frac{1}{4}$, and $5\frac{1}{4} \times 4\frac{1}{4}$, with no change of the super except the different number of T tins used. Besides, the T tins are less likely to fall out of their places with the L tins. A serious objection that outweighs all these advantages is seen only when you come to take out the sections *en masse*. In taking out the sections the superful may be considered as one solid mass, and the only resistance to be overcome is at the outer boundary of this mass where the sections come against the rim of the super. You will readily see, that the more nearly you apply your force to the outer boundary of your section mass, the more easily you will remove them. If you don't see it readily, just try it. Now, with your L tins the follower must be kept distant from the side of the super a distance at least equal to the width of the horizontal part of the L tin, making just so much of a tendency for each section in the outside row to separate from its next neighbor, and wedge itself against the side of the super. By making the supports for the T tins detached, as I use them, I am enabled to have the follower larger, so as to come under the whole bottom of the section, by simply cutting out places in the follower for the square sheet-iron supports to pass through; thus:

FOLLOWER FOR
EMPTYING
THE T SUPER.

FIG. 1.

I tried a continuous piece for a support instead of the detached pieces, but rejected it after trial. A minor objection to the continuous piece is, that it shuts off the outside openings for the bees to pass up into the sections (in the case of pound sections, closing two of the seven openings), leaving, instead, a convenient place for the bees to fill with propolis, thereby increasing the difficulty of removal. If, however, I were obliged to use the L tins I would fasten them on

thus:

instead of thus:

FIG. 2.

FIG. 3.

That is, I would have the bee-space at the top instead of the bottom of the super. I never tried your plan, but I studied over it carefully. My hives are made like many others, with a bee-space on top of the frames, so that it is more convenient on that account to have the bee-space at the top of the super. But if no bee-space were on top of the frames I think I would make one there by putting a little rim around the top of the brood-chamber so I could have the bee-space at the top of the super. Perhaps I can explain why. It is

impossible to make your work so exact that the distance from the L tins, when nailed on to the upper edge of the super, shall be always and everywhere precisely $4\frac{1}{4}$ inches; moreover, the lumber in the super may shrink, even if only a very little; and, besides, a bit of bee-glue, or a slight variation in the size of a section, may make a difference. In either of these cases you may have something like this:

FIG. 4.

The upper surface of the sections being higher than the upper edges of the super:

Now, in tiering up (and I wouldn't use these supers if I couldn't tier them up) there will be difficulty in placing another super on this one, for it must fit *exactly* over these sections, with some liability of injuring the sections, both in putting on and taking off the upper super. On the other hand, if the bottom of the sections rests flush with the bottom of the super, any little inequality such as I have mentioned would produce no worse result than simply to make the bee-space a little smaller.

Speaking of the T tins made of two pieces soldered together, you say: "These are just as good when finished, but are rather expensive to make." Mine cost nearly twice as much, I think, as you offer them at, but I think they are by no means "just as good." In filling a super, when the last section is being put in, it sometimes catches on the sharp edge of one of the T tins, and makes trouble about getting in; whereas, in your T tins the rounded edge will not be so likely to catch and hold the section from going in.

There is an advantage in having the T tins movable that you have not mentioned. It is, that it is so very easy to put in all the sections except the last ones, as you will readily see that, for the first three rows, you can have the space to put them in as loose as you please; whereas, if fixed, all the spaces will be equally tight. Moreover, in putting in the last sections (the most difficult ones, whether the T tins are fixed or movable), if the T tins are movable, the sections, tins and all, can be crowded along so as to make more room, so I think a super with movable tins can be filled more quickly and easily.

My supers are made with the corners double-halved. This not only makes a stiff close corner, but it is very easy to nail together right. Yours, however, being made of thinner stuff, will not admit easily of halving at the corners, and, as I understand it, yours are to be used *inside*. Mine being of $\frac{3}{8}$ stuff, there is never any thing outside the super, which is simpler and cheaper, I suppose, but perhaps there may be some advantage in the extra protection yours have.

The inside length of yours, if I mistake not, is $\frac{1}{2}$ inch less than mine, there being in mine 50 per cent more play lengthwise with the pound sections than in yours. I am a little afraid that, with so little play, some will condemn the super as being too difficult to fill.

Yours are $1\frac{1}{8}$ inches wider than mine. I suppose that is to make them fit the hive. Mine are too narrow to fit my hives, and it is awkward; but I thought I would rather put up with the awkward-

ness than to have them larger. Still, there is room for difference of opinion about this. But please let me insist *very strongly*, that, if you make the inside wider than $12\frac{1}{2}$ you will make it still wider than $13\frac{1}{2}$, and not stop short of at least $14\frac{1}{2}$. Mine are $12\frac{1}{2}$; and let me assure you, from a big experience, that nothing less should be used for a width of six sections measuring $1\frac{1}{2}$ each. I know you can take figures and prove me all wrong, but I have gone through all of that, and thrown away supers because the fit was too tight, so I think I know what I am talking about. Now, if I am right, that $12\frac{1}{2}$ is right for 6 sections, and you make your super $13\frac{1}{2}$, you have just $1\frac{1}{2}$ inches space in which to crowd a $1\frac{1}{2}$ section. I am not sure but that figures may help a little. Seven sections make $7 \times 1\frac{1}{2} = 10\frac{1}{2}$. Add to this, for six wooden separators, $6 \times \frac{1}{2} = 3$, and you have $13\frac{1}{2}$, so you must count on $7\frac{1}{2}$ shrinkage to get them in, if every thing went just by the figures. But in actual practice it doesn't work just by the figures. I wish for once you would be urged by what may seem to you my prejudices. If you make the supers too loose, no great harm will come of it; but if too tight, the result will be worse than you perhaps think, as I know from sad experience.

The more I think about it, the more I don't like the idea of having the super inside the hive. In a busy time in a large apiary, I think it will make extra handling that should be avoided. Is there any real advantage in it? Perhaps you think the supers will not fit nicely on the hives. Mine do not, but the difficulty is easily overcome in actual practice.

C. C. MILLER.

Marengo, Ill., Feb. 21, 1887.

On receipt of the letter above, I wrote to Dr. Miller in substance as follows: We aimed to adapt our super to the Simplicity hive as far as it seemed practicable. In doing this we made one or two slight changes. It is true, your bee-space in the T super is above the sections. We made ours below. The construction of the Simplicity hive necessitates a bee-space under the crate, as there is no shoulder to raise it a bee-space above the frames. You are perhaps aware, that most of our customers are using the Simplicity hive. This brings the sections flush with the top edges of the super; but with our improved machinery it does not seem to me that there will be very much trouble arising from inaccurate work. We think of nothing that would support the T tins as firmly as the L tins. It is true, we could make short pieces of L tins; but we fear that, if we should do this, these small pieces might be lost in packing; and, besides, they would not be as strong.—The inside width of the T super ($13\frac{1}{2}$ in.) is just the same as in the combined crate and Moore crate. In both we use $1\frac{1}{2}$ sections; and in the former, $1\frac{1}{2}$ sections, with tin separators. If we use *wood* separators we have no doubt but that you will need the $12\frac{1}{2}$ -inch space for six $1\frac{1}{2}$ sections. The $1\frac{1}{2}$ when first made will always shrink enough to let in tin separators. There is no way of using wooden separators in our T super unless we use narrow sections.—In regard to the L tins preventing the bees from getting into the last row of sections, would not contraction, as prac-

ticed by yourself and others, obviate the difficulty in a great measure? For the most part, the bees would have a tendency to pass directly into the central rows of sections from the brood-nests. ERNEST.

Dr. Miller replies as follows:

I have looked your letter over carefully, and will now consider the different points. First, you adapt the T super to the Simplicity hive. If nearly all your customers use Simplicities, there is weight in this. In settling upon it for my own use, however, I thought it of first importance to have the super just right, and if the super in that shape was not adapted to the hive, why, then the hive must be adapted to the super. The super is no more adapted to my hive than it is to the Simplicity, so I adapt my hive to the super; and if I had Simplicities I feel pretty sure I would not change the super, but adapt the hive to it. If I understand it rightly, your super is to sit directly on the frames, and I feel pretty sure that, after you have once tried this, and also tried the slat honey-board, you will never again do without the latter. You see it is different from using wide frames. In that case the bits of comb are built between the brood-frames and the wide frames, leaving the sections clean. But in the case of the T super the bits of comb will be fastened directly on the sections, and each time that a new super is added in tiering up, the freshly added sections will, in their turn, be built under with bridges of comb. Now, this is simply unendurable; and I think, when you look over the whole ground fully, you will agree with me, that, for this super, the slat honey-board is nothing more or less than a necessity. If you agree with me in this, then it will not be a very difficult thing to make a slat honey-board that will fit the Simplicity hive and accommodate perfectly the T super. In other words, the honey-board will serve as an adapter. This frees us from the expense of an outside shell, but in its place we have the expense of honey-boards; but as we must have the honey-board anyway, we need count only a small part of the cost of the honey-board—just what it costs extra (if any thing) to make it fit the super. Keep in mind all the time, that, by so doing, we leave the super in perhaps its best shape, and ready to be used on any hive. This latter, however, doesn't count for much, if any thing, for the super as you propose it can also be used on any hive. By the way, I would, I think, have a honey-board for the S. hive with a lower beveled edge to fit the hive, and the top level to fit the super.

Your objection to the square sheet-iron pieces instead of the L tins (being lost in the packing) is a valid one; and you might have added, that the L tins are much easier put on. But in packing, if the number of pieces be small they can be wrapped in stout paper and nailed on. If the bee-space must be at the bottom, then I would still use the sheet-iron pieces, putting them on L shaped.

You ask if contraction, which I and others practice, will not obviate the objection, that the L tins will hinder the bees from passing directly into the outside row of sections. The greatest objection, at least one of the greatest objections to the system of contraction, is that it prevents the bees from being directly under all parts of the super, unless dummies be used between the brood-frames to make the brood-nest wider. If I had only three frames in the brood-nest I should just as much

want direct passage into the outside row of sections, in order to encourage outside work, and I would then have the three brood-frames under one side of the super; and after work was well started in the one side of the super, reverse (not invert) it and let them start in the other. The bees will find abundant room to enter at center of super, but I would rather close some of the central entrances and force the fullest use of the side entrances, so as to induce equal work in all parts of the super. I may say, in passing, that the contraction business may not be a permanent affair.

You say no complaint has been made of the width of the Moore super. Were not the Moore supers used without separators? Even with tin separators, some difference in width would be needed. After largely trying both wood and tin separators, both in wide frames and T supers, I could not be induced to use wood on wide frames, and I would object almost as strongly to tin in T supers. I am using wood separators, having thrown aside thousands of tin, occasionally using a tin one where the fit is unusually tight. Wood is warmer than tin; and when used loose in a super it keeps straight where tin would bend. Moreover, a width that would just do in a Moore super would be too tight for a T super; that is, if the Moore super is what I have called a Heddon super. In the Moore super, if a section is started in at all, it can be crowded down into place, as the wooden wall on each side keeps it right in its place. On the other hand, in the T super, if tight, the edges of the sections will slip by each other, and will also catch on the T tins. As I think more about it, I object seriously to having the supers hold more than 24 1-lb. sections. I would rather have them smaller than larger. (I forgot to say, that I think the large majority of your customers use tin instead of wood separators because they have been in the habit of using tin on wide frames, and have never tried wood. After trying wood I think they will prefer it where the separators are not nailed on.) Whilst I do not believe as much in contraction as some do, I hardly think you will want to run more than seven or eight brood-frames while supers are on; and I know from troublesome experience that it is very undesirable to have the super wider than the brood-nest. Bees will not work nearly as well in that part of the super which has no brood-frames under. If the super must be 13½ inches in width, then I would put in only six 1-lb. sections in width, and fill up the empty space with a follower fastened with double-pointed wedges like this:

E. S. Armstrong, and perhaps others, use this arrangement, and I rather like it.

I think I shall hereafter use T tins on top as well as under the sections. It will cost an additional three cents per super, and they will hold the sections more smoothly in place, and also prevent the bees from daubing propolis on the sides of the sections.

Referring to page 51 of "A Year Among the Bees," at the bottom you will see I covered supers with quilts. The past season I used with great satisfaction 50 wooden covers on the supers, and shall use them entirely the coming summer. It is simply a plain cover as wide as the super, and as long, or a little longer, made of ¾ pine, cleated.

FIG. 6.

The principal reason for using this wooden cover is because, when using the sheet or quilt, the bees very freely propolize the tops of the sections, and this board allows a bee-space on top, so that the bees leave the sections nearly clean—another reason, you see, for having the bee-space on top. If there is to be no bee-space on top I would still use this board, having a $\frac{3}{8}$ rim on the board to make the bee-space. No other cover is put on top of this super cover.

C. C. MILLER.

Marengo, Ill., Feb. 28, 1887.

The above correspondence between Ernest and Dr. Miller touches on several important matters connected with the matter of getting comb honey. Now, the experience of a man who has raised honey by the tons, and first-class honey too, is surely worth something. Another thing that is encouraging, is, that a large amount of correspondence in regard to this matter of T tins and T supers agrees remarkably with everything Dr. Miller has said. Let us take up the different points one by one.

T TINS, AND HOW TO FASTEN THEM IN THE SUPER.

The general opinion seems to be, that they should be movable, and that they should be used on top of the sections as well as below. Second, they should be supported in such a manner as to allow the bees access between the side of the super and the outside row of sections. The plan given by Dr. Miller above is perhaps as good as any. To prevent losing the six little pieces of iron alluded to, I would by all means nail them in their places, even when the supers are sent out in the flat. This is quickly done in the factory where the cases are made, and saves valuable time for the buyer. They pack just as closely, and there is no possibility of being lost or mislaid.

SHALL THE SUPER BE MADE SO THE BEE-SPACE IS ABOVE THE SECTIONS OR BELOW THE SECTIONS?

With the evidence given, I should say have the bee-space by all means above the sections, then use a plain honey-board on the super, and the friends who have complained so much about the trouble of closing the bee-space between the sections of the top-most super will have their problem solved. Mats, enamel sheets, or quilts, are not desirable, for they soil the tops of the sections, and cause the bees to put on more propolis than the plain honey-board with the bee-space above.

USING A SLATTED HONEY-BOARD IN CONNECTION WITH SUPERS.

The slatted honey-board should be by all means used. Ten or twelve years ago I abandoned the T-super arrangement, principally because of the comb attachments between the brood-combs and the bottoms of the sections. We owe friend Heddon a vote of thanks for having stirred us all up to the

importance of some sort of a honey-board between the sections and the brood-frames, in order to avoid these attachments.

HAVING A COVERING TO PROTECT THE SUPERS FROM BOTH FROST AND SUN.

Here is a point where Dr. Miller and I shall have to disagree just a little. Some years ago I made such very full and complete experiments in trying to decide whether the chaff hive was an advantage in winter as well as in summer, that I think I can not be mistaken in thinking we should get more honey in a well-protected super than in one exposed directly to the weather, especially where there are cracks admitting rain and wind. I verified it again in the house apiary, by having the bees build and store comb honey in sections protected by good warm covering, and without any protection except a piece of ducking. I repeatedly caused the bees to commence storing and stop storing in supers by putting a close warm box over them and taking it off again. The fierce heat of the sun would stop work, and within a week or ten days cold nights would stop work; whereas, if an outer hive or box confined the air at such a time, work would go right along. Colonies of equal strength were tested side by side, and more bees went to the fields, and more pounds of honey were gathered, where protection was given. Almost any bee-keeper can test this by using chaff hives side by side with hives made of inch boards. Another thing in favor of using Simplicity hives: There are thousands, and may be hundreds of thousands, in actual use in all parts of the world. We have ourselves for a number of years sold ten or fifteen thousand annually. One reason why we sell so many is because we make every thing to match these hives in actual use. A great many times something has come up, seeming to make it desirable to change them—this matter of eight or ten combs for a hive, for instance, and the changes back and forth from comb to extracted honey. Almost invariably, however, in a few months we have reason to be glad we did not change our machinery and methods. If there seems to be a great advantage in using hives with only eight frames, I think by far the cheapest way will be to put in a dummy or dummies, as friend Miller does himself, and let your hives remain all of one size outside.

HAVING A SUPER NO WIDER THAN A BROOD-NEST, AND A BROOD-NEST NO WIDER THAN A SUPER.

I believe friend Miller is about right in this matter. With better protection for his supers, however, such as the chaff hive gives, I think his bees would work just as well and he might perhaps get from ten to twenty per cent more honey by letting the super be wider than the brood-nest—say about an inch or two on each side. The season might have something to do with it, however. I have repeatedly seen a powerful colony working on 80 sections in a chaff hive, all at once, and the sections that did not stand over the brood-nest seemed to be filled almost as quickly as the others. I think the reason is because the bees are so

thoroughly protected from the extremely hot sun, as well as from the very cool nights. We are now making T supers exactly as Dr. Miller recommends, only they are made of lighter stuff, on account of the outside protection afforded by the chaff hive, or by additional stories of the Simplicity hive. There are more pieces to handle in getting a crop of honey, I admit, but I think the extra amount of honey received because of this protection will pay for the extra labor.

ARMSTRONG'S REVERSIBLE T SUPER.

SHALL WE REVERSE THE T SUPER?

FRIEND ROOT:—I send you to-day a sample of my reversible T-tinned honey-rack, or section-case. I find it is giving great satisfaction. I know it is a little more costly than yours; but then, I can get at my sections singly much easier than in yours, but perhaps that will not cut any very great figure among practical beekeepers. Inclosed you will find a description of the same.

E. S. ARMSTRONG.

Jerseyville, Ill., Feb. 28, 1887.

NEW REVERSIBLE SECTION-CASE.

The above cut shows my new reversible section-case. It is made with loose, adjustable T tins, so arranged as to keep the sections straight and clean. It can be adapted to wide frames if desired. It holds 24 $4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{1}{2}$ sections, 5 thin wooden separators, and 2 adjustable following-boards, all being held firmly in place by my double clamping-wedges. It can be used without separators if desired, as the separators rest on the tins, and are not fastened to any thing. It is perfectly reversible, having the loose, adjustable T tins on both sides, and in every thing else being exactly alike it is always right side up, and the upper side is always the side to open. If you wish to reverse or remove one or more sections singly, you have simply to unbutton the upper holder, which will liberate the T tins and give you free access to any section in the case.

Friend Armstrong has sent us a sample of the reversing T super described above. We are constantly receiving a great many reversing supers, but we are free to say that we have not seen any thing that seems to be better constructed for reversing than this super. Our readers will notice by the cut that the T super has the T tins above and below the sections. There is certainly a great advantage in having the T tins above. In the first place, it keeps the bees from propolizing the upper corners of the sections. In the second place, it holds the sections square, or, in other words, two sets of T tins above and below, make the space between the sections, both at top and bottom, equal, thereby accomplishing one of the good features named for the Moore crate, but with

this advantage: It permits the use of separators. Friend Armstrong has also two followers, a plain board of the size of one of the wooden separators which he uses in the case. These plain boards are used at the extreme outsides of all the sections in the case. A space is thus left for a wedge, as seen in the engraving, and as mentioned by friend Miller elsewhere. We believe there is quite an advantage in having the sections pressed up tightly, as it closes the interstices between the sections, and, in consequence, it is claimed that the bees are less liable to propolize where the sections come together. The manner in which friend Armstrong has constructed his case for reversing is quite ingenious. There it no "right side up" to the case. It can be used just as well one side up as the other, and, as our readers will see by the above engraving, the sections may be easily removed. Now, we would hardly like to say so many things in favor of friend Armstrong's case had it not, we believe, Dr. Miller's indorsement of one or more of its features.

We have considered the good points in this case, so let us now consider some of the weak points which might be named against it. First, its construction is rather complicated. There are four pieces of wood for each side of the shell, making, in all, including the two ends, ten pieces. The button arrangement for removing one of the sides is very neat in the sample sent, but we fear it will be difficult to construct it in all cases so that it will work as nicely as might be desired. It seems to us, then, that the case will be rather too expensive for the majority of our bee-friends, who, with the low price of honey, are aiming to reduce the cost of producing honey to the minimum. We doubt whether it pays to go to the extra expense of making a case invertible for the possible advantages it may give. We believe, too, that a great many, if not a majority, of those who once advised inverting, are, to say the least, not now so ardent in its praises.

DOES IT PAY TO GO TO MUCH EXPENSE IN EXHIBITING HONEY?

MORE ABOUT MARTIN'S HONEY-EXHIBIT.

FRIEND ROOT:—I have received some inquiries relative to the honey-exhibit in a late issue of GLEANINGS, and will, therefore, give a few further details. In your comments upon the exhibit, you probably echo the sentiments of a great many others when you question the advisability of spending time and money in making such an exhibit; or, in other words, the question resolves itself into this: Does it *pay* to spend time and money to advertise the honey-business? If we look around us, we see every trade making strenuous efforts to get ahead. Take up the most obscure county paper, and every trade is represented in its columns. Our most successful merchants are the ones who "catch on" to every advertising novelty to be used in the extension of their business. The leading merchants in a thriving village set up mile boards with their name upon them, for 20 miles into the surrounding country. Our fairs are

the red-hot centers of attraction and advertising. Near my exhibit was a display of wall-papers. A room about 12 feet square was built, and decorated with expensive paper; and so it is through all lines of business, with the exception, perhaps, of bee-keeping.

Probably the hardest thing for a spirited bee-keeper to bear, at the present time, is the general belief that bee-keeping is a small business, and that any ninny who knows just enough to chew gum can successfully produce honey; and bee-keepers, as a rule, are following a course of action to confirm people in that belief; for if a business is not worth a little advertising effort, it is not much of a business. And right here, friend Root, I wish you would insert the cartoon found on page 347, Vol.

IMPENDING BANKRUPTCY.

VII. of GLEANINGS. It fully expresses the general idea the bee-keepers of this country have in relation to advertising their business. That is the great trouble with our markets, and the sale of honey; it is the sit-down, do nothing, good-for-nothing, waiting-for-something-to-turn-up policy. Our Canadian brethren are away ahead of us in the line of exhibits at fairs; and at our recent convention at Albany this fact stuck right out when it was mentioned that, in Toronto, the honey-exhibit piled up to twenty tons, and the exhibit in our own great State of New York, the Empire State of the nation, at its last annual fair, was twenty pounds! Now, my dear N. Y. State reader, look at the above cartoon; does that chap look like you? If he does, look yourself in the face and blush.

Our Canadian brethren, finding that it pays to exhibit twenty tons in the home country, incurred a great expense by shipping forty tons to England to exhibit, and they found their enterprise richly rewarded, not only in present sales, but in future markets.

A like fair for the exhibit of products from the United States will be held during the coming season, and I don't hear any thing about the honey-business being represented, and it probably will

not be, unless some of our magnanimous commission merchants take hold of it; and I will leave it to the reader to infer how much the producer will be benefited thereby. There is some excuse for us, however, as the exhibit comes in a season when a first-class exhibit would probably be impossible.

I commenced this article to describe certain parts of my exhibit. Our Canadian friends have written me kind words of encouragement. I find that the log cabin has special charms for them, and I have been requested to explain how it is made.

The front is a thin board, 18 inches wide and 30 inches long; the Jones half-pound cans are attached to this with No. 30 tinned wire (such as we use in wiring frames). The end is 20 by 18 inches, with a gable. These two parts, after the tins are fastened on, are hooked together. A board covered with fdn. is put on for a roof, and it is set so the vacancy in the rear can not be seen, and it passes for a very good log cabin, and is easily made. The tins that are put on with wire are, of course, empty; the upright tins and pails can be filled if desired. The pavilion is also easily made. The main work is upon the wooden frame. It is made so as to be taken apart for shipment. In fact, the whole exhibit is made with that end in view. A very little time (and less money) was expended, as it was made for show and not for permanence. J. H. MARTIN.

Hartford, N. Y.

Friend Martin, I give up; I guess you are all right. The expense of your exhibit, come to understand it, is not as great as I supposed, and I had entirely forgotten about the great (?) exhibit of the State of New York. I suppose, of course we should be consistent in these things. A large bee-keeper, or one who has tons of honey to sell every season, could better afford to make an exhibit that would astonish the people, than the one who may have more enthusiasm but less cash or experience. What I had in mind was the danger of letting our enthusiasm lead us into *unwise* expenditures.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

THE T SUPER WITH TINS AT FIXED DISTANCES.

I HAVE used your T supers, figured in last GLEANINGS, on Heddon's 8-frame hive, for two or three years, with the T stationary. I make the T one-half inch longer than the inside width of super, which, turned bottom up before you, space off for length of sections on edge of side piece. Make fine saw-kerf in those spaces, but slanting, so as not to show on outside; drive the body of the T right down into the kerf; and as it laps on to each side piece $\frac{1}{4}$ inch, you can nail each $\frac{1}{8}$ -inch-wide flange, that the sections rest on, to what will be the bottom of sides. They appear quite firm before being nailed. The sections will, of course, be on a level with the bottom of the crate, so you will have a bee-space on the upper side of the crate; and for the one below, depend on the one in the wooden honey-board or hive. You readily see, that fastening the ends of the T in this way makes them much stronger than when flopping loosely around. It also avoids your two pieces of angled tin strips the

whole length of the crate. I use two flat strips of tin, $\frac{1}{2}$ inch wide, same length of T's, nailed on to bottom of ends of crate, projecting inside $\frac{1}{8}$ inch. I have 64 swarms with this arrangement, and 33 with the combined crate and 10 frames, but I like the 8-frame and the T super far better.

Watertown, N. Y., Feb. 21, 1887. JAY DIMICK.

THE T SUPER—A SUGGESTION.

I am making a T super for the L. hive, so that I can bring the two outside rows of sections to the center of the brood-frames, by making the supers six inches wide inside (according to size or width of section), or one-half the width of the hive. By changing sides with supers this brings the outside rows in the center. It is a great drawback to have the two outside rows of sections unfinished, which has for a long time kept my mind and eye open for something to solve the problem. I think I have found it. I shall give it a thorough trial this season. Any person can make this and use it, or give it a trial, and report.

WILL ELLIS.

St. Davids, Ont., Can.

Many thanks, friend Ellis. Your idea of turning the outside rows of sections in the T super so that they come over the center of the brood-nest is ingenious. The only difficulty I see in the way, is the additional expense. I am not sure that the advantages from changing the outside rows of sections in the T super, as you describe, will pay for the extra cost. You know we want to produce our honey with the least outlay of money possible. The bee-keeper who produces honey at a minimum cost is the one destined to make the most clear gain. You notice that the T super, which we illustrated on page 156, is made just as cheap as any thing can possibly be made—simply an outside shell, and the T and L tins.

ITALIANS, HYBRIDS, AND BLACKS.

We purchased 15 colonies last spring at an auction. Three were pure Italians, five pure blacks (as you call them), and the rest hybrids. We increased them to 55 and took a little over 2000 lbs. of surplus, 1400 of comb, and 600 of extracted; but, as usual with me, the hybrids were ahead in the amount of honey gathered; the blacks came out next, and the Italians were far behind. The Italians are, with me, poor comb-builders. They will make too much drone comb, and put too much honey in the brood-chamber; and as I use only starters, either above or below, these two faults would outweigh, with me, even if they did make a little more honey. My blacks are much the most pleasant bees to handle; but with me a black queen and an Italian drone produce the best-natured bees I have ever handled, and they are the best workers. Indeed, I never had any trouble with cross bees in my old apiary until I purchased Italian queens, and yet my bees were nearly half yellow by means of my neighbors' Italian drones. From what I read in the papers, and from my own experience, I conclude that there must be a great difference in the native bees of America, called "blacks."

H. V. TRAIN.

Mauston, Wis., Feb., 1887.

WHAT MADE THE BEES SO CROSS?

I should like to know what made bees so cross in 1886. I had three stands of Italians, and they got so cross that I could not handle them at all. I went to

take some honey in the month of July, and they tried to sting me to death. They even left the hive and went to the barn, which was three rods from the hive, and got on my hogs, and I had to go and get my hogs out of the pen and put them in the barn, or they would have been killed.

HENRY BOGARDUS.

La Fontaine, Ind., Feb. 19, 1887.

Friend B., I can not suggest any reason, but that the bees had suddenly ceased to find honey in the fields. As a general thing, they are gathering honey in most localities during July. Toward the close of the month the basswood often fails quite suddenly; then the bees, instead of being full of honey, are loafing around the hive, comparatively empty and cross; and at such times you should not attempt to take their honey, or do any thing with them. Take the honey away before the yield has closed up, and you will find them peaceable and gentle. Even a colony of full-blood Italians, when they get stirred up at about this season of the year, will sometimes leave the hive, and almost chase one off from the premises.

THE BINGHAM SMOKER, AND HOW TO USE IT.

With this I mail you a "Doctor" smoker, such as I have learned to consult when in need. It is not likely that you will like it at first. Artemas Ward said, that "habit is a bad habit." It will, however, perhaps, win its way to a good practice after becoming familiar with its patients. It will require lots of wood, and, in turn for this trouble, will allow you to slowly send a vast volume of smoke just over the hive in which you wish to find a queen, so slowly and so carefully as not to startle the bees, yet so ample as to give them a realizing sense of who their master is. This controllable feature I think you will learn to like.

Probably why I like so much smoke in the air about me is, that the bees have much respect for me, when so surrounded. This fact, no doubt, you have fully and well learned. I never use a bee-veil, as it is such a burden, and renders bee-work so tiresome. Yet it probably is a fact, that we use more smoke in our apiary than is used in any other, of a similar size, in the U. S.

We are able to work fast, as we do not have to "subdue" bees (as filling the hive with smoke is called, etc.); so much smoke in the air answers just as well, and we think much better, and saves more time than the stovewood costs. You will find maple and ironwood the best fuel for easy use. When you wish to quit work for the night, a gallon jar or crock partly full of water will be a good safe place to put the coals the smoker may contain—one thing you will sometimes find handy when all the smoke is gone from the coals. Hot air is as good as smoke for the control of bees.

Abronia, Mich., March 1, 1887. T. F. BINGHAM.

Your smoker was received, and it certainly is well and substantially made. There seems to be nothing in its construction that will "play out" soon. As you suggest, and I think, too, owing to habit, I did not like it quite as well as the Clark on first trial in the apiary this spring, but perhaps after I have tested it more thoroughly this summer I shall change my opinion somewhat.

ERNEST.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: *Sheep Off, Silver Keys, The Giant-Killer, or, The Roby Family, Rescued from Egypt, Pilgrim's Progress, and Ten Nights in a Bar-Room.* We have also *Our Homes, Part I., and Our Homes, Part II.* Besides the above books, you may have a photograph of our old house apiary, and a photograph of our own apiary, both taken a great many years ago. In the former is a picture of Novice, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

CONDUCTED BY ERNEST R. ROOT.

THE BOYS' BEE-HIVE FACTORY. WINDMILLS AS A MOTIVE POWER FOR HIVE-WORK.

AFTER the events recorded in our last, the boys could talk of nothing but windmills, before and after school, and at recess; in fact, I am afraid their studies suffered more or less from it. They inquired of everybody they knew who could give them any information about windmills. In the meantime, Mr. Green had talked with some of his friends who were skilled in the mechanic arts in regard to this same matter. He had also sent for a couple of price lists of those having windmills for sale. Ere long the two price lists came to hand; and after fully considering the possibility of the boys making a windmill, Mr. G. invited Jimmy over one evening to talk with him and Sam. Jimmy needed no second invitation; but before the appointed time he was on hand. Mr. G. then produced the two catalogues, accompanied by a couple of letters, for he had made some inquiries of the manufacturers in regard to the proper size of a mill for doing light buzz-saw work. When Mr. G. could get the boys quieted he began:

"Upon some inquiry which I have made, I find that about one horse-power is required to run a buzz-saw suitable for average hive-making work, and I have been told that even a half horse-power will answer, providing a light-running arbor, with a thin, well-sharpened saw is used; and providing, too, that the saw is not crowded too hard with $\frac{3}{4}$ stuff. I think on the whole, boys, if you make a windmill at all you ought to calculate upon at least a half horse-power. It is true, this will not give us power enough to work to the best advantage; but I think it will be enough for you boys. Now, then, what size of mill is necessary to produce this power in a fair wind?"

Mr. G. then requested his wife to bring him the two catalogues from his secretary.

"There," said he, pointing to a picture in

one of the catalogues representing one of the improved windmills; "the diameter of this mill is 17 feet, and it is rated at three horse-power."

"Whew!" said Jimmy; "if 17 feet in diameter will give three horse-power, then—let me see; 3's in 17 $5\frac{1}{2}$ times. Why, a windmill to give one horse-power would need to be only $5\frac{1}{2}$ feet in diameter—purty near six feet; and fer half horse-power—"

"Jimmy," said Sam, interrupting, "you are clear off your base. I should think the power of a mill would be in proportion to the number of square feet of surface."

After rummaging around, Sam found a piece of paper and a pencil, remarking, "What is the use of going to school, unless you can put it to some use?"

Mr. G., in the meantime, looked amused, and finally spoke:

"Boys, you are both wrong, though I must admit that Sam is nearer right. You must bear in mind, that the larger the mill the more purchase the wind will have upon the center; and that, while the power of a windmill is, to a certain extent, as to its number of square feet of surface, this matter of greater purchase must be taken into account. Let me see. You have not studied philosophy yet, have you? but you both know how much power you can exert on the end of a crowbar. Now if the crowbar were shortened it would give you a great deal less purchase, would it not? The proper size of the mill we can not get at, I think, by means of figures and comparison, in order to produce a given horse-power, so I think we shall have to trust to the experience of those who have made windmills. One of the manufacturers writes me that a mill 12 feet in diameter would do tolerably well for running a buzz-saw for hive-making. We will, then, take this for our basis. Supposing that a 12-foot windmill will run a buzz-saw in a fair wind, and yet do good work, we will then reason that, if we desire to use a very light-running arbor, with a thin, well-sharpened saw, and that the saw will not be crowded too hard, an 8-foot mill in a good stiff breeze will probably do *your* work."

Mr. G. then showed the boys an old *American Agriculturist*, telling all about how to make a cheap windmill, the cuts and diagrams fully explaining each part of the mill.

"Now, I want to say, boys, that this business of making windmills has generally not proven to be very profitable; but as you are so desirous, and seem so determined to make one at all hazards, I propose to let you have the necessary lumber, and you can tinker away to your hearts' content. But I don't believe you are quite mechanics enough to construct a good windmill; however, spare evenings I will assist you in some of the most difficult parts of its construction."

The following day being Saturday, when there was no school, the boys set to work with a keen zest. They worked, assisted by Mr. Green, for several weeks, nights and mornings and Saturdays. During its construction I fear their minds were on the windmill the greater part of the time, even in school hours. Sam's teacher noticed something was wrong, as he didn't get his

lessons as well as usual. Sam was called to account, but he "didn't know what was the trouble."

At last the windmill was completed, and erected on top of the barn. Every thing was finished, though a skilled mechanic could easily detect the work of a boy's hand in some parts of its construction. Mr. Green did not think it was as strong as it might be, but he thought it would do if no very severe winds should strike it. The next evening the boys waited for the wind to come up. Jimmy grew impatient, and expressed himself as follows:

"Confound the luck! if we did not want the wind to blow it surely would, and knock things all ter pieces; now we've been waitin' here fer two hours and it won't budge. I'm goin' to get up there and turn that thing around. Mebbe it needs greasin'. Perhaps if we coax it a little it will start."

So saying, Jimmy clambered up on top of the barn and thence on to the windmill tower. He turned the mill around and around, but it wouldn't coax at all. Mr. G. finally advised the boys to wait for the wind to blow, which it probably would do before evening; but this did not pacify the boys much, and so they kept waiting until they were late for school. Just before recess the teacher announced that Jimmy and Sam should stay in at recess for tardiness; that they should both come to him and report why they were late.

That evening, after school, although the boys had been called to account for misdemeanor, they bounded homeward almost out of breath. Sam, however, did feel a little mortified, both because he was called to account for neglecting his studies, and because he had never been punished before. Jimmy didn't care a "red cent," as he expressed it; "twasn't nothin' to stay in at recess." When they reached home they saw that the windmill was yet standing still, and apparently not a breath of wind was stirring.

"Ho, ho, there!" called out Jake, one of the schoolboys, just passing by, and whom the two boys particularly disliked. "That thing wouldn't run if there *was* any wind. If I couldn't do better 'than that, I'd sell out. Ye had ter stay in at recess, didn't ye?"

Jimmie was on the point of going over to "lick the stuffin out of him," but Sam's mother appeared just then. She advised the boys to wait till morning, and perhaps there would be a breeze.

To be continued April 15th.

JUVENILE LETTER-BOX.

"A chief's amang ye takin' notes,
An' faith, he'll prent it."

DAMP CELLARS AND DAMP BEE-HOUSES.

We have been having a nice winter, and plenty of snow for sleighing. We had 10 colonies last year, and they did well. We put two of the weakest of them in the cellar, and the rest of them outside, and packed them in pea straw around the outside. Bees should not be put in a cellar if it is damp, for it is

not healthy for them. We made a building for the bees, and put them in for one winter; but it was so damp and warm that they all died. Last year we got 450 lbs. of honey. Basswood was an entire failure.

ROBERT McCURDY, age 12.

Hornby, Ont., Can.

20,000 LBS. OF HONEY FROM 200 COLONIES.

My brother keeps bees. He has 200 swarms. They made 20,000 lbs. of honey last summer. I have a cat, and his name is Tip. Pa has a dog, and his name is Snider.

BERTHA KING, age 9

Bryantsburgh, Iowa.

OWNERSHIP.

My pa gave me a stand of bees last summer. He keeps them in the cellar for me. Next summer I am going to try to take care of them myself. My pa has 23 stands of bees.

Pharisburg, O. DAVID A. SHENEMAN, age 11.

See our promise to the little folks, to be found elsewhere in this department.

ASILUS MISSOURIENSIS, AS REPORTED BY A LITTLE GIRL.

It is a beautiful day to-day. The bees are out having a fine time. We have had a very mild winter here, with but few stormy days. Papa thinks this is a splendid country for bees, only, of course, being in a new country there is a lack of bee-pasture. We have one valuable bee-plant here, called the sensitive rose. In the summer the fields of the sensitive rose look like large fields of red clover. There is a bee-killer (*Asilus Missouriensis*) that troubles us a great deal. I have often seen large numbers of wounded bees creeping around on the ground, and I have caught the bee killers with the bees. They catch the bees in their talons, or fore arms, and then stick their bill in the poor bee and get the honey. You will find the exact picture of this insect in Cook's Manual, page 268.

NELLIE FAY, age 12.

Franklin, Neb., Jan. 26, 1887.

Thank you, friend Nellie. The facts you have given us are interesting and valuable. We like to have bright-eyed little girls report upon some such item as this. In the last edition of Prof. Cook's book the cut of this interesting long-named insect appears on page 317 instead of 268. We like to reward boys and girls who are able to call these queer bugs by their right names, so we send you a large panel chromo.

A JUVENILE INVESTMENT THAT PAID.

I am 11 years old, and I live on a farm. Papa said that the first swarm of bees I saw come out I could buy, and pay for them this fall; also the hive, frames, sections, etc. The bees made 64 lbs. of honey. I sold the honey for \$8.00. After I had paid for the bees I had \$3.00 left. I sold nearly all my money to papa, and got the cash in gold. Papa wants me to learn to buy and sell. I learned to clean the sections and frames, and I can put foundation in frames, and fold sections. We have no bee-house for our bees, but pack them in straw in a long row for winter. We tack an old carpet in front of the entrance, to keep it dark and to keep out the snow, wind, and cold. We do not have to disturb them all winter. We have boards in front of the chaff hives to break the wind. It was fun to climb the apple-trees and hive the rousing swarms. I can pick up a

drone in my hand. I cleaned all the sections and frames last fall. I can nail frames. I go out among the bees with bare feet and hands. I can help carry a hive of bees easily. We learned quite a lesson last summer in bee-keeping, that cost us a good hive of bees. It was a strong swarm of bees. It made a lot of honey, and swarmed three times. The last swarm had four queens. We saw them go in. The old hive was the last hive on the row, but papa set the new hive right beside of it, within about five or six feet. The new hive was just like the old one, and now it was the last one in the row. The bees in the old hive were in the habit of flying into the last hive in the row, and must have made a mistake and flew into the new hive as they came from the fields. The queens must have all gone with the last swarm, and they failed to raise a queen. They became so weak that the other bees began to rob them. We had a fine time with robbing in the apiary.

ARTHUR BOSSEMEYER.

Dixon, Ill.

Many thanks, my young friend, for your good report. The investment certainly was a profitable one, was it not? You are not only \$3.00 ahead in cash, but you have a good swarm of bees, and, more than all, a stock of experience that will be worth something to you in your future investments of this kind. These habits of enterprise we like to encourage. We will here give notice to the little folks, that our promise, as made on page 317 last year, still holds good. We there agreed to send any girl or boy, who could send in a *good* report as the proceeds of his own work, and *his own* bees, for the past season, a beautiful panel chromo. By the conditions of this promise, I think, friend Arthur, you are fully entitled to the present, and we therefore send you one. We shall be pleased to hear from other little boys and girls who can give us a report of what they did with *their own* bees; and if you sold your honey, where and how you did it.

TOBACCO COLUMN.

A CHANGE OF MODUS OPERANDI.

MY father-in-law, with whom I have spent the last month, is a bee-keeper on a small scale. He never smoked bees, but often smoked himself and other people with a pipe. Now, he has determined to change his modus operandi by smoking bees instead of people. I have every reason to believe he has abandoned tobacco for ever, for he is persecuting the weed among his neighbors with a vim that but few people can muster. Please send him a smoker; and if he ever smokes tobacco again I will pay you for a dozen bee-smokers. I am myself a "great past-master smoker," an enemy to tobacco—hardly ever known to raise a flag of truce—no, never.

ANTHONY JOHNSON.

Essex, Ia., Jan. 29, 1887.

Many thanks, friend J. We wish there were more like you.

John Trego wants you to send him a smoker to this office, and agrees, if he uses tobacco again, to pay you for it.

E. LISTON.

Virgil City, Mo., Jan. 27, 1887.

A YOUNG FRIEND HAS QUIT.

I have a friend addicted to the use of tobacco, with whom I have been laboring to have him quit, and he has finally consented to leave it off. He is a fine young man, just beginning the management of bees. I will see that you get your pay for a smoker if he takes it up again.

E. VAN FRADENBURGH
(Pastor Baptist Church).

West Fulton, Scho. Co., N. Y., Jan. 12, 1887.

HAS USED TOBACCO ALL HIS LIFE.

I used tobacco in various forms all my life until the past six months. I have now abandoned the weed altogether. I am very willing to pay the price of the smoker should I ever use tobacco again.

E. B. JOHNSON.

Manatee, Fla., Nov. 18, 1886.

I have never used tobacco to any great extent, but I have smoked cigars frequently. For over six months I have quit the use of tobacco; now, if I am entitled to a smoker, please send me one, and if I smoke again I will pay you the price of it.

Boscobel, Wis., Jan. 22, 1887.

C. V. MAIN.

I prevailed on my brother, on the 1st of Jan., to quit using tobacco, telling him you would send us a smoker free of cost. If he ever uses tobacco again I promise to pay you for the smoker.

Hillsdale, Mich., Jan. 7, 1887.

W. L. HUNKER.

Mr. Elihu Baimbridge told me that, if you would send him a smoker, he would quit smoking and never use tobacco again. If he does he will pay you for the smoker.

A NEIGHBOR.

Farmington, W. Va., Feb. 5, 1887.

Mr. M. M. Jones, one of my neighbors, has quit the use of tobacco. He quit the last of September, and says he never intends to use it again; and if you still give a smoker, please send him one as a reminder of his resolution. He has used tobacco for many years.

R. L. PATTEN.

Cooper Sta., N. Y., Feb. 1, 1887.

Thanks, friend P. The more neighbors you induce to give up the weed, the better.

Please send me a smoker for quitting the use of tobacco. If I ever use it again I will pay you for two.

FRED BASSETT.

East Kendall, N. Y., Feb. 8, 1887.

I used tobacco for ten years, but have not used any for three months and I do not think I shall ever use any again. If you will send me one of your smokers, and I commence using the weed again, I will pay you for the smoker.

HENRY REINHEIMER.

Callicoon, N. Y., Feb. 7, 1887.

I was telling my neighbor, Mr. Green, that you would give a smoker to every man who would quit using tobacco. He has quit, and promises to pay for the smoker if he ever uses tobacco again, and I will vouch for it. He has used tobacco for a number of years, and is confident that it does him a great injury. His old father has quit using tobacco. He has used it since he was a boy. He does not ask for a smoker. His health is better than it has been for a good many years.

Fleetville, Pa., Feb. 8, 1887.

C. D. FARNHAM.

OUR HOMES.

Then Simon Peter answered him, Lord, to whom shall we go? thou hast the words of eternal life.—
JOHN 6: 68.

SOME of us are great talkers. We express every thought and feeling by our words. Others talk very little. They may suffer keenly, and you would hardly know it, or they may feel joy, and give little expression to it. I have sometimes thought, however, that where one is in the habit of using but few words, these few words often carry the greatest weight with them. Sometimes half a dozen lines express more than pages could tell. It is to half a dozen printed lines that I wish to call your attention in this Home Paper. I have read these half-dozen lines over and over again, and each time I read them that old prayer of mine comes up of itself, "Lord, help." Here is the letter:

Friend R:—GLEANINGS came to me yesterday, and found a solitary bee hovering over the coffin-lid of my darling, darling wife. Oh, tell me! can there be any sweetness amid all this bitterness?

Yours in sorrow,

G. C. STOKELY.

Arnoldville, Ind. Terr., Jan. 14, 1887.

The plea goes up for help, not for myself, but for our suffering brother. The lines themselves at first glance tell very little; but as I read them over they seem to say to me something like this:

Our friend has been a bee-keeper. He has been in the habit of sharing the joys and pleasures of bee culture with the companion of his home—with a companion given him by God—sent him by God, as it were, to make his life happy and pleasant. According to the commandment which God has laid down in his holy word, they twain had become one. What a beautiful partnership is the relation existing between man and wife! We all crave companionship; and if there be one in the world who can find happiness without the companionship of a single human being, he is an exception to the general rule—a sort of abnormal human being. There are those who may content themselves a while off alone; but sooner or later they want somebody to talk to—somebody for company. And what more beautiful relation can there be than the relationship between a good man and a good woman? The marriage-rite tells how it is—they are to help each other, to cheer and encourage each other, and to study each other's happiness; and as the years go by the attachment is to become stronger and stronger, and they are to become more and more unselfish, each one losing sight of self in making the other happy.

Some little time ago, Maud and I were visiting one of her old college schoolmates. This schoolmate was united to the man of her choice, and they had just moved into a neat little cottage of their own planning and building. He was thinking and talking of his wife most of the time, and she was thinking and talking of her husband most of the time—not in a silly way, but like two good pure-minded people, or, if you choose,

a good and pure-minded boy and girl. The sight was a pleasant one to me. At the table, I was, of course, asked to give thanks; and while doing so my heart was filled with the thought of how much these two had to thank God for. As we were about to retire I made the remark to my young friend, "Did it never occur to you, friend—, that a good pure woman is the greatest blessing that God ever bestowed on man?"

His countenance brightened up at once as he took in the thought, and replied, "Indeed it is, Mr. Root; and I believe you are right, that the greatest gift God ever bestowed upon man was woman."

Let us now go back to the letter. GLEANINGS has been a welcome visitor in that household. Possibly they two have sat under their humble vine-covered porch, and looked over its pages. May be they have together "got acquainted" with A. I. Root through its pages, and, possibly, learned to love him just a little; but may God grant, that through him they have learned to love the Savior more! Well, a number of GLEANINGS comes as usual on one of its semi-monthly visits. The weather is warm in Indian Territory, even during the middle of January—at least, warm enough so the bees are out a little. Perhaps the hearts of these two have oftentimes been cheered by the little winged busybodies in the depth of winter, and there is nothing very strange in the fact that a solitary bee was buzzing about when this number of GLEANINGS was handed in, right from the postoffice. The sight of GLEANINGS, as well as the solitary bee, might bring a thrill of pleasure to our friend's heart at any other time, but how is it now? Where is that bright, cheery, joyous inmate of his household now? In scarcely more than a line he tells us of the sad, sad story. Probably attracted by the varnish of the new piece of woodwork, this solitary bee has called. It is only a simple piece of wood covered with newly applied varnish. But what a story it tells! It is the *coffin-lid* of the darling wife—the great gift that God gave to friend S. has been suddenly called away. As I read the lines over, and realized that it is possible—nay, quite probable—that I may have to go through such an ordeal, up comes that old prayer again, "Lord, help!" Lord, help me when I shall be called upon to endure a trial like this! As I think of it, I feel weak and cowardly. For a little time I begin to wonder whether even the religion that I taught so earnestly would help me to be trustful and manly, were I tried as friend S. has been tried. May God forgive my want of faith and my human weakness when I contemplate such a trial! My mind runs back to the old days of more than a quarter of a century ago, when I first began to get acquainted with the priceless gift God had then in store for me. I remember our foolish, childish actions when we first began to get acquainted. I remember the hours and hours that we wasted in trivial things. *Were they wasted, dear reader?* I am almost afraid, if I should see two young people now doing the same thing I should be tempted to say they were wasting their pre-

cious moments. But how do you know that it was not laying the foundation for this sacred relationship? It takes a good while, my friend, for a man and woman to know each other perfectly.

A few days ago we were studying the Sunday-school lesson where it told of Abraham and his son Isaac. My wife asked the question, "Wasn't Isaac frightened when his father was making preparations for that sacrifice?"

I replied, "The father trusted God. The boy was a 'chip of the old block,' and trusted God, and also trusted his father. What his father had decided to do, he knew by years of experience was right; both father and son were preparing to obey God, fearing naught."

"But," said my wife, "have we any illustrations nowadays of such a faith as that?"

I replied, "How about yourself and your four-year-old boy? Do you suppose that any thing you could do would frighten him?"

She replied, "To be sure, it would not, for he *knows* his mamma, and his mamma *knows* him." And she turned to him lovingly. Now, one of the most beautiful sights in this world, to me, is the love between mother and son. Boys, especially small boys, need a great deal of mother, and they get it too. I have often thought of it; I have often watched the looks of love and confidence and faith that passed between the two. The little man tells by his look that he loves his mother more than all else in the world—more than all the world together, in fact. Father, brothers, and sisters may be near, but none of their names have the fullness of that endearing sound, *mother*; or, if you choose, "*my ma*." The mother, too, for the time being—at least while the boy is in his dresses, perhaps just getting ready for different clothes and a different field of action—getting ready, as it were, to go out into the world—during this period the mother's whole soul and all the capabilities of her nature are poured out on this boy. Now is the critical period. If he loves and *obeys* his mother now, he will probably not only love and obey her always, but he will love and obey God also. The love the mother has for the father is a different kind. The father can take care of himself; but the child's whole future life, almost, depends upon her. God has given this embryo man into her care and keeping, and God holds her responsible.

Please bear with me, friends, if we study a little further this relationship between parent and child—between a good mother and a child who loves this mother, and has implicit faith and confidence in her. It is sometimes the duty of the mother of our little home to punish our four-year-old boy. Now, does this punishment break the union of faith and confidence that exists between them? By no means. He seems to recognize, as it were, that the punishment is necessary. I have seen the conflict going on in his little heart between good and evil, and I have seen him put his little arms about mamma's neck, almost before the tears were dried, and say by actions, if not by words,

that: he has no other friend in this wide world like that mother; and on her part, when she punishes, that the great absorbing love that she has for her boy is in no whit abated. It is on account of that love that she punishes, and because she has prayed for him, and is praying in her heart, that she does it. Present ease is nothing to her, compared with the great broad future. She wants him to be a good man—an evenly balanced, intelligent, and useful man; and she knows he can not be this if he goes through life crippled by an uncontrolled evil temper or selfish and evil impulses. Sometimes when he is talking with me he tells me of these conflicts. His childish words are something like this:

"Ma punished me, she did."

"Why, papa is real sorry to hear that. Why did mamma have to punish her boy?"

"Cause, I was naughty."

"Well, you are not naughty now?"

"No, I am good boy now."

You will notice from the above, that there is no unkind feeling—no thought of disputing the mother's right. His faith and confidence in her are so great, that, even if he did not understand it entirely, there would be no hard feeling toward his own mamma. We don't always know what is going on in these little hearts. Sometimes we totally misunderstand; and if there is any place in the world where we need to have great charity and much forbearance, I think it is in the care of children. Mamma once asked me to talk with Huber when he seemed to be stubborn and willful. For quite a time he did not reply, and I began to think he would have to be punished. Finally I thought I would see if I could not win his confidence, and get him to tell me his *reasons* for his misconduct. At length he made a statement that seemed to me so unreasonable I decided at once he was untruthful. His childish heart grasped the idea, and he looked me full in the face while he repeated his statement, and ended it with a phrase he had probably heard some of the children use—"In 'honest troot' I *don't care*, pa." He seemed to be grieved, and to be in real trouble and almost anguish because his papa did not believe him. Then I saw that the misunderstanding and stubbornness were all explained by the fact that he had a wrong understanding of the meaning of some of the words he had been using. But I had caught a glimpse into that little soul, and I understood him perfectly. He meant, "I *didn't mean* to." I presume I shall always remember it, and the way he looked up to me as he said, almost with a sob, "In honest troot."

Now, friends, what a sad and grievous thing it is for a parent and child to misunderstand each other. Friends are sometimes estranged by misunderstandings, and by being in haste to conclude that the other has deliberately committed a wrong. Such things are sad; but to misunderstand a child, and to scold him when he is not guilty, is a grievous thing. When punishment is added to the little innocent unconscious offender, it is sadder still. Such things usually come about by want of faith

and confidence in each other. Misunderstandings between parent and child are sad to contemplate; but, my friend, they are sadder still when they arise between husband and wife. If the relationship between those whom God has joined together is a beautiful one, how very sad is the contemplation of misunderstandings and hard feelings between these two.

The few brief lines in our afflicted friend's letter tell us the relationship between him and his wife was of the kind I have tried to picture. Harmony and happiness—perhaps the greatest happiness God has given to mankind—was theirs, and now she is gone. God has called her home, and left our friend sorrowful and alone. And now for the last line of that letter. Bowed down with grief, and a grief that seems to have blighted the whole of his nature, our friend breathes forth this wail, wrung from his heart by the keenest anguish. Can there be any sweetness amid all this bitterness? Dear friend S., I can not promise you that all at once this load of sorrow shall be lifted; but we can promise that there will be sweetness come out of it—perhaps a higher and purer joy and peace than you have ever yet known; but it must come through submission to the divine will. Remember, dear brother, what it was that brought forth those immortal words—"Thy will, not mine, be done." It was the Savior who uttered them in contemplation of the trial he was about to undergo. He prayed that the bitter cup might pass away, but ended the prayer, "Nevertheless, not my will, but thine, be done." Let no murmuring thoughts enter your mind. Beware of looking about you and comparing your lot with others who have not thus been called upon to endure such trials. Put your trust in God, and bring your grief to the feet of the Savior; even though you may not understand the reason of all this, dear brother, do not question or waver. Let your relation and your trust be like that which I have tried to picture between husband and wife, or between mother and child. Say to yourself over and over again, "He knows best;" "it is the Lord."

For your encouragement, let me tell you of some cases I have known. When my father was taken away every one was astonished to see my mother bear it not only patiently but almost triumphantly. Although several years have passed, even now there is no subject on which she can converse—no subject that seems so bright and full of happiness to her—as that of his death. People talk about the loved ones having only gone on before; but in her case it is a reality. She speaks of it as something to rejoice over. He is in glory, and she will be with him soon. Many people, even her own children, thought it was unnatural, and they thought there would be a reaction soon; but no reaction has ever come. Again, a few months ago one of the young men employed in our factory died suddenly. Nobody thought of such a thing as his slight sickness being fatal. A messenger came to me while I was in jail, Sunday afternoon. I was stunned and bewildered by his words—"Mr. Root, N—W—

is dead." I started at once, wondering how I could comfort the grief-stricken parents. Their eyes were full of tears; but I was surprised to see smiles shining through the tears. The mother seemed even happier than I had ever seen her, and I have known her for many, many years, and, thank God, she has always been a trusting, faithful disciple. The joy that shone forth from her face was caused by the fact that, with his last words, he told them he was resting in the Savior's arms, and why should they lament or be cast down? His experience had not been as bright as that of some others, and he was not much given to talking, especially on such subjects. His words were mostly brief, like those of our poor friend who writes the letter. When he came to die, the few brief sentences he spoke to his mother as he breathed his last had enough of heaven in them to make her rejoice for the rest of her life. I have talked with her since, but she always makes me ashamed of myself, because her faith is so much brighter and stronger than mine. "Why should I be sad or sorrowful?" she says; "I have prayed for him these many long years, and now in a strange and unexpected way God has answered the prayer. He has taken him home, to be with the Savior, and he is safe—safe through all eternity; why should we lament?"

The mother punishes the child because he has been disobedient. We can not always say, however, that God punishes us because we have been disobedient. In fact, Christ's own words declare most positively that misfortunes and afflictions and grievous trials are *not* sent to those who are most sinful.

And Jesus answering said unto them, Suppose ye that these Galileans were sinners above all the Galileans because they suffered such things? or those eighteen upon whom the tower in Siloam fell, and slew them, think ye that they were sinners above all men that dwelt at Jerusalem? I tell you, Nay; but, except ye repent, ye shall all likewise perish.—LUKE 13: 2, 4, 5.

Therefore, dear friend S., we have no right to presume that you have in any way been remiss. We all must meet death, and we must all part with our loved ones, sooner or later. The rain falls upon the just and upon the unjust. The only important thing in this life is to have that full and perfect trust in God I have tried to tell you about. The little one I have used as an illustration shows by his actions, "I love my ma, even if she does punish me;" and we should say, in the language of the old patriarch Job, "Though he *slay* me, yet will I trust in him." This trust should in no sense prevent us from doing all in our power to avert calamity and affliction. We know, dear friend S., although you have not told us, that you did all in your power to save the life of the darling wife who is gone. But this matter of life and death is beyond our control. The best physicians the world affords have admitted their helplessness over and over again. Death, like the winds and waves, is in the hands of the almighty Father. At his word they obey; and he only can kill and make alive.

We are not told that the old patriarch Abraham was filled with peace and joy as

he started homeward after that wonderful journey off into the wilderness with his son Isaac; but we are told that God was exceedingly pleased with him when he had tried him and found him faithful; for he says, "For because thou hast done this thing, and hast not withheld thy son, thine only son, that in blessing I will bless thee, and in multiplying I will multiply thy seed as the stars of heaven, and as the sand which is upon the seashore. And in thy seed shall all the nations of the earth be blessed, because thou hast obeyed my voice." Friend S., I don't even know that you are a Christian; but somehow I feel, from your brief letter, that you are, in any case, not far from the kingdom of God. I have sometimes thought that great affliction brings men into the kingdom when nothing else would. Skepticism and infidelity have nothing whatever to offer you. A young man who was quite talented, and who had studied pretty deeply into skeptical writings, said, in our young people's prayer-meeting, not very long ago, "If there is any thing in this world that is unsatisfying to the soul of man, it is skepticism and infidelity. These writers would take away every hope—knock out every prop, and leave the hungering and thirsting soul in a vast sea of doubt in unbelief, and in place of what they have taken away they give nothing—*absolutely nothing*." These may not have been his exact words, but they were the substance of them. The only thing that is satisfying amid trials like these is the gospel of Christ Jesus. It says, "Come unto me, all ye that are weary and heavy laden." Poor Peter was right when he spoke the words of our text. At that time the multitude seemed to decide that the teachings of Jesus were too strict and exacting; they cut off too many things that the Pharisees delighted in. The path was too straight and narrow, and the people turned away. Even many of his followers, we are told, went back and walked no more with him. Jesus turned to the twelve—the tried and the faithful ones—and in sadness said, "Will ye also go away?" Peter, outspoken and ready as he always was, made haste to answer: "Lord, to whom shall we go? Thou hast the words of eternal life." And I pray you, dear brother, in the name of Christ Jesus, to cast your burdens on the Lord. He, and he only, has the words of eternal life. No other one in the wide universe can speak peace to the one who stands where you do. Since the world began, no one except those who came in the name of Christ Jesus have been able to bring solace and comfort to the dying-bed. Yes, there is sweetness for you. The peace that Christ can give is yours for the taking; and the promise of eternal life may be yours if you will accept it as a free gift, and the promise of again seeing the loved one beyond the grave. It is true, God's holy word does not tell us very much as to what the future shall be; but those who study it diligently will find promises that are every thing the human heart can ask for. If Jesus, on the mount of transfiguration, talked with Moses and Elijah, why shall not we meet face to face,

and talk with the loved ones who have gone before? Christ is the way, the truth, and the life. And there is no other way that ever has been opened, or that ever will be, to poor humanity, when called upon to endure the trials and afflictions of life.

In II. Corinthians 9:7 we are told that "God loveth a cheerful giver;" that is, he is pleased with those who submit in humble obedience to his decrees; and to be cheerful givers we must have that loving faith and trust. We read, also, that Abraham believed God, and it was counted unto him for righteousness. Skepticism may tell you there is no remedy for trials like these; infidelity says there is no escape—no opening—no help in this wide universe; but I tell you, friend S., there is hope, and there is a remedy. God, who gave this gift, still rules the universe, and he is still a loving Father. It is not probable, it is not likely, it is not reasonable, that the Being who planned this universe as we see and comprehend it should plan such trials as yours, with no opening and no escape. God the Father wants us to look away from these things toward him. The first of the ten commandments reads, "Thou shalt have no other gods before me," which is, in effect, "I am to be first and foremost in the affections of my children. I am the beginning and the end, I am over all." The invitation to come to him and to seek him in trouble as well as in joy rings forth clear through the whole Bible. "Like as a father pitieth his children, so the Lord pitieth those that fear him."

Now, my dear friend, it is not true that God has left you uncared for. Jesus tells us that not a sparrow falls to the ground without God's care; and, again, he tells us that God so loved the world, etc., as you have probably read over and over again. He has not forgotten you. He is not unmindful of your sorrow, but he is ready and near. In the very last words of the Bible we read, "And let him that is athirst, come; and whosoever will, let him come." I pray you, my dear friend, let there be no misunderstanding in your heart; let there be no doubt, no want of faith. Say on your bended knee, "Here, Lord, am I, a poor grief-stricken, cast-down child of thine. Here am I, feeling that the light of the world has gone out. Have mercy on thy poor stumbling and doubting servant. Take thou me into thy care, and keep and help me to say from my heart, 'Thy will, not mine, be done.'" And, dear brother, if you can say it, try to add, "Tell me, I beseech thee, what thou hast for me to do in this world. If it be thy will, I will try to be happy again in trying to make others happy. Take me as I am, and teach me thy ways." In the little book used by Moody and Sankey there is a hymn composed by one who, like yourself, saw nothing left on earth to live for. She sat down in helpless sorrow, and apparently gave up. In fact, so great was her grief that she begged God to take her out of the world. The little hymn is apparently his answer. It was written after she found joy and peace, and probably greater happiness than she had ever known before—

probably greater happiness than she could ever have known had the loved one been spared to take all her thoughts and attention. Yes, it is even probable that, had he lived, he might have taken her thoughts away from her Creator. Here are the lines:

Not now, my child, a little more rough tossing,

A little longer on the billows' foaming;

A few more journeys in the desert darkness,

And then the sunshine of thy Father's home.

Not now; for I have wanderers in the distance,

And thou must call them in with patient love;

Not now; for I have sheep upon the mountains,

And thou must follow them wherever they rove.

Not now; for I have loved ones sad and weary;

Wilt thou not cheer them with a kindly smile?

Sick ones, who need thee in their lonely sorrow;

Wilt thou not tend them yet a little while?

Not now; for wounded hearts are sorely bleeding,

And thou must teach those widowed hearts to sing;

Not now; for orphan's tears are quickly falling,

They must be gathered 'neath some sheltering wing.

Go, with the name of Jesus, to the dying,

And speak that name in all its loving power;

Why should thy fainting heart grow chill and weary?

Canst thou not watch with me one little hour?

One little hour! and then the glorious crowning,

The golden harp-strings, and the victor's palm;

One little hour! and then the hallelujah!

Eternity's long, deep thanksgiving song!

think it over calmly you will find your old friend has some redeeming traits after all. I do not believe we are really greedy. We like to have things straight and square, and have an understanding, but we surely do not want a single dollar that rightfully belongs to you or to any other brother. Now, after thinking the matter over, don't you believe you have been just a little rough on your friends at Medina?

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,

EDITOR AND PUBLISHER,

MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, MAR. 15, 1887.

Every one that hath forsaken houses, or brethren, or sisters, or father, or mother, or wife, or children, or lands, for my name's sake, shall receive a hundredfold, and shall inherit everlasting life.—MATT. 19: 29.

THE DESCRIPTION OF THE NEW FACTORY, ETC.

A PART of the above was written by Ernest and a part of it by myself—or, rather, I have put in a paragraph here and there. Those who are expert in such matters may be able to pick out the portion dictated by myself and that dictated by Ernest.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

OUR friends will notice that the above is not given in this issue. One reason for its omission is, that there seems to be more interest in other matters just now, so we have occupied this space with matter pertaining directly to bee culture. Another reason is, I have felt as though I needed more practical experience myself, before attempting to teach others in some of the lines I have proposed taking up. The book, as far as it has gone already, (128 pages), will be furnished by mail, bound in paper covers, for 75 cts.; if ordered with other goods by freight or express, 70 cts.

We are pleased to notice "*The Bee-Keeper's Record*," published in Scotland. It is conducted by W. B. Carr and William Raitt—the former of Cheshire, England, and the other of Blairgowrie, Scotland. We are a little surprised to find it in its fifth volume, and we don't remember that we ever saw a copy of it before. It seems to me our old friend Raitt is a little backward in letting the world know what he is up to. In a word, the *Record* is a very neat and interesting journal of apiculture, and we consider it quite an addition to our bee-literature. The subscription price is 2s. 6d per annum. We presume that either of the above friends will be glad to receive subscriptions from America.

TERRY'S POTATO-BOOK—THE APPENDIX.

This appendix is now printed, and has been mailed to all purchasers of the Potato-Book. Although it cost us altogether something like \$50.00, it is added to the Potato-Book without any further increase in price; viz., 35c, or 38c if ordered by mail. The

GROWLERY.

SOMEbody has complained that we don't have any more Growlery lately; that is, we put in all the kind words and kind notices that we get, and don't give anybody a chance to speak at all when things are not as they should be. Well, I don't know but I shall have to plead guilty, but it has not been from a disposition to misrepresent, but because of neglect; and, in fact, we have only two letters suitable for this department, and they are quite old at that. Here is the first:

If you have not shipped those crates I ordered, you need not send them. You were too slow. I could get four orders from Mr. Newman, of Chicago, while you send one. Please send me the money, and I will not bother you with another order.

W. A. ZIEGLER.

Logansport, Ind., June 24, 1886.

Whew! If the above is a tremendous clip at A. I. Root, it is a pretty good recommendation for Bro. Newman, at the same time. And this reminds me, that there are few people who do business, of whom we hear as little complaint as of our friends of the A. B. J. Now, friend Z., your order was received June 14, right in the very height of the season, and your goods were shipped on the 24th. I know that ten days is almost too much, but it seems to me it is not so very bad after all: Here is the other:

I find a notice on last GLEANINGS, that you like to have another dollar. Well, you can't have any more of me, because you are not gentleman enough. You are all too greedy. Stop your GLEANINGS! I am sorry I ever had any thing to do with you. You are all money.

P. DIEHL.

Durand, Wis., July 4, 1886.

I will explain to our readers, that friend D. was displeased because a compositor set his name wrong in the subscription-list; and the consequence was, he got a dun when he did not owe us any thing. Now, friend D., I am exceedingly pained to hear you say you wish you had never had any thing to do with us. May be, after you

appendix considers cheap potato-diggers and high-priced potato-diggers; having growing crops such as rye and clover on the ground every month in the year; how to raise potatoes without either hoe or harrow; the potato-blight of 1885; the bes. knife for cutting potatoes, after two years of trial; the \$25.00 disk harrow; additional thoughts in regard to seed potatoes. It comprises eight pages and three illustrations. The potato-book has had a wonderful sale, and seems to please remarkably. Many reports are now coming in from those who have made a success by following the teachings of this little book. Here is one just at hand:

Please send the supplement to Mr. Terry's A B C of Potato Culture. With the aid of this book I raised from one-half bushel of seed, 35 bushels of fine Peerless potatoes, many weighing two pounds apiece. I could pick five bushels with no potatoes under one pound. I prepared the soil thus: First, plow; after that spread manure from the stable; then harrow. The manure mixed better with the soil being spread after plowing. After good harrowing, then follow with a plow, and harrow again. I am 68 years old, and one-legged. If I can do it, any one else should who is sound in limb, and not crippled in mind. P. C. BLUHM.

Smithville, Tenn., March 7, 1887.

Here is one more, that comes from Sweden:

As for the A B C of Potato Culture of Mr. Terry, I dare say, all the world has to be thankful to him. It will revolutionize the way of cultivating this crop. In the last year several people in this country have tried it, and received a crop by it 1-7 more than the largest told of in the A B C. It is just enormous. H. STAHLHAMMAR.

Gothenberg, Sweden, Jan. 27, 1887.

ECONOMY IN DOING EVERY-DAY TRIFLING DUTIES.

How often we do things by laborious hand-work, when a very little ingenuity would devise a simple machine for doing it in one-fourth of the time, or less! In a large factory this is almost continually coming up. Just now one of our shorthand writers is greatly crowded; and while thinking about economizing her time I noticed that it took her quite a spell in the morning to whittle her leadpencils. It is true, there are pencil-sharpeners in the market, but she says they are not practical. I took two dozen pencils in my hand, and in a few minutes the foreman of our saw-room had fixed a sand-paper wheel so as to whittle them beautifully, about as quickly as you could pick them up and lay them down again. When the two dozen need sharpening, we propose to go over them again, and so on. A great many times I see quite expensive hands, or sometimes a very valuable boss carpenter, waste his minutes by whittling a pencil. My friend, if you are called upon to employ high-priced workmen, see to it that they are not required to use the time in such like trifling duties.

BEE-JOURNALS BOOMING THE BEE-BUSINESS—IS IT RIGHT AND PROPER?

In my opinion, it is not right and proper for any industrial journal to present only the bright side, and urge everybody to go into said business, in order that they may get subscribers and sell supplies. Catalogues of things that manufacturers or producers have for sale are expected to present the encouraging features of the industry, or of their special wares; but industrial journals should give all sides of the subject—encouraging and discouraging. They should meet fairly and squarely every difficulty in the way. Whenever I have an opportunity it is a pleasure to look over the medical journals of our land. These journals are published for the express purpose of assisting and enlightening the medical fraternity; but, do they try to induce *everybody* to hang up a shingle, and start out as a doctor? Of course, not. What an idea! Well, I believe our bee-journals should be conducted much in the same way. Of course, more peo-

ple go into poultry, bees, etc., as a rule, than into medicine; and in view of the fact that a great many, when they find themselves properly situated, feel like keeping a few bees or chickens, our poultry and bee journals should meet this want; but I am sure that none of us wish to lead people into disappointment, but, on the contrary, we wish to give a fair understanding of these industries to all who may care to inquire.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

THE CONDITION OF OUR BEES; CHAFF CUSHIONS, ETC.

SOME of our readers seem to be anxious to know the *exact* condition of our colonies; to what extent brood-rearing has commenced; whether foul brood has made its appearance for this season. The weather being warm and spring-like on the 9th and 10th of this month, we critically examined all the colonies. In the previous issue, we stated that we pulled up one corner of the burlap, and looked upon the clusters of all the colonies; but we did not then pull the colonies apart. I did not then, and do not now, think that it would have been any advantage to pull the colonies all apart, as they were in such nice, compact clusters. Subsequent examination has shown that hardly half the colonies have commenced brood-rearing, so that I think we should have found very little brood. By "hefting" the frames too, we knew that the bees were not running short of stores. Now, after having gone over the apiary the second time, and examined every comb, I doubt not that our readers are waiting to know whether foul brood has reappeared. I wish I could say that no trace of it had developed; but I am compelled to inform our readers that a very bad case of the disease was found—I think, perhaps, as bad as any I have yet seen. I judge they must have commenced rearing brood along last February. The diseased brood was well advanced, and the characteristic odor from the hive, as soon as we opened it, was unmistakable. An examination showed that the combs were badly diseased. We found this colony among the first that we examined, and this state of affairs certainly was not very encouraging at the outset. Myself and two of the men then set to work in earnest, determined to discover any more traces of foul brood if there were any. After a vigilant search through the entire apiary on the following day, we found that all the rest of the colonies were sound and healthy; and, as we had confidently hoped and expected, not one of them has died from wintering. Had it not been for this one aggravating case of foul brood, we should have reason to feel greatly rejoiced, although we are well aware that we may lose some yet.

Now, what did we do with this one case of foul brood? We did just what we would advise anybody else to do who feels confident that there is *only one* diseased colony in the apiary; that is, we burned the hive and all.

We left the foul-broody colony till evening. The air being then nearly at the freezing-point, we pulled off the hive-cover, the chaff cushion and all the other covering, from the bees, leaving them exposed to the freezing air. Our reason for doing this was that the bees might become so chilled as to render them unable to fly while being conducted to the boiler-furnace. On the following morning I went down a little after sunrise, and expected to find the bees pretty well chilled. Not so. As I advanced to take out the frames, a couple of surly little fellows struck me in the face. However, I picked up several frames as quietly as possible, being careful not to cause the bees to fly into the air, and threw them into the boiler-furnace, where their fate was very soon sealed. I had to make two trips in order to take all the bees. While doing so I observed that three or four bees, possibly a dozen, flew into the air. As I felt somewhat apprehensive that they might return to other hives in the immediate vicinity of the one I proposed to take away, I allowed the diseased chaff hive to stand in its location during the day. Of course, I expected the flying bees to return to the old location, which I discovered they did do the following evening. I then consigned the hive and all to the flames. Had I taken away that hive as I have done on previous occasions, I feel sure that they would have entered other hives, and so would have communicated the disease to three or four more colonies neighboring and adjacent to their own hive. This is not mere theory, for sad experience has taught me the truth of this statement.

CHAFF CUSHIONS.

We believe our readers have never seen a good cut of the chaff cushion, which we use and like so well in our apiary. Our engravers have taken the pains to make a correct picture, and here it is:

CHAFF CUSHION FOR THE TWO-STORY CHAFF HIVE.

The covering is burlap. You notice that it is made square, so as to fit tightly and snugly in the corners of the hive. This we regard as important, as it prevents cold drafts of air from circulating down into the brood-nest. These chaff cushions should be filled so as to be comparatively loose, as seen in the engraving. If they are filled too full they will present a convex surface on both top and bottom; and the corners, in consequence, will be drawn out so as to leave an air-space in the corners of the hive. We believe, from our observations this winter, that too much tightly packed chaff is rather a detriment than an advantage, because it does not allow the moisture to pass off as readily. Those who desire any further in-

formation in regard to this chaff cushion, and how to make, we would refer to the A B C book.

T TINS. AND IS THERE ANY LIABILITY TO BEND OUT OF SHAPE?

I have seen it suggested in one of our journals, that one very great objection to them was that the T tins were liable to get bent. I feel pretty sure that, if the parties who offer this objection would try by actual experiments the strength of the T tins they would never again say that the tins were fragile. To test the matter we took two T tins and placed them in such a way that their ends rested on a couple of projections. A weight was attached so as to draw equally on the center of both. A light weight was first used, and increased as it was found that they would stand the burden. At 80 lbs. weight the tins bent sideways but not downward. If the T tins had been fastened so they could not have sprung to one side or the other, the same as in the T super, I think they would hold nearly double that weight.

Now, then, all the weight that each T tin is required to hold in actual usage can not be more than 6 or 7 lbs., and I think that no amount of ordinary usage could bend them out of shape, as the test above shows that each T tin would hold 40 lbs. and more before giving way.

SINGLE-TIER CASES AND THEIR ADVANTAGES.

As there has been a great run on the single-tier shipping-cases, we have had our engravers illustrate what we call our 24-lb. single-tier shipping-cases. Our readers will perhaps remember, that about a year ago we gave a cut of what we called the 12-lb. single-tier shipping-case. The former is designed to take the place of the 24-lb. double-tier case which we have now discarded, though we still sell the 48-lb. double-tier case. For the benefit of some of our new readers, I will reiterate a few of the points named in favor of the single-tier case:

First, the N. Y. commission men recommend them. They are much lighter to handle, and, in consequence, are much less liable to breakage during shipment. Moreover, a single-tier case of honey is much more salable, for the reason that it shows off the honey to better advantage than the double-tier. In the former, only the central and best portion of the honey is exposed to view. Furthermore, the double-tier case is open to the objection that, if any of the top row of sections become daubed, the lower ones will become soiled with drippings.

If any of the readers are desirous of knowing the price of any of these implements, we would refer them to our list.

SPECIAL NOTICES.

MAMMOTH SWEET CORN.

We have raised such a fine crop of this seed, which has been carefully dried by steam heat, and kept warm and dry, even up to the present time, that we are prepared to make the following low rates on it until the seed is exhausted: 1 pint, 5c.; peck, 75c.; $\frac{1}{2}$ bushel, \$1.25; one bushel, \$2.25. If wanted by mail, add 15c per pint.

REDUCTION IN THE PRICE OF WHITE DUTCH CLOVER-SEED.

We have reduced the price of white Dutch clover-seed to \$10 per bushel; \$5.50 for $\frac{1}{2}$ bushel; \$3.00 per peck; 22 cents per pound. This is one of the staple honey-plants, and we take pleasure in giving you the above prices for the seed, which is much lower than we have ever furnished it before.

THE WARNER CHAIN AND SCREW ATTACHMENT FOR SAW-TABLES.

We have received so many inquiries in regard to this improvement on saw-tables for hive-making, illustrated in Feb. 15th GLEANINGS, page 154, that we write this to let you know we can furnish the attachment, with 10 feet of chain complete, for \$5.00. This can be attached to almost any saw-table, and will greatly aid you in keeping your gauge set in the right place.

THE LADIES' FRIEND AND GOSHEN CARPETS WEEPERS

By a misunderstanding with the manufacturers, we have offered the above at a less price than we ought to have done. Hereafter the Ladies' Friend will be \$2.00, and the Goshen sweeper \$3.00 each. On two sweepers, however, we will allow a discount of 5 per cent; three sweepers, 10 per cent; six sweepers, 20; and for twelve sweepers, 33 $\frac{1}{3}$ per cent. The orders may be made up of either kind or both. The World sweeper will be sold for \$1.50.

MAPLE SYRUP.

We have now in stock toward 100 gallons of the finest maple syrup I believe we ever handled. A part of it is made with the ordinary boiling-pans, and another part by the improved evaporators, such as Prof. Cook describes. As there are some people who prefer syrup made in the old way, we have decided to put the price at the same figure; viz., \$1.10 per gallon, package included. In lots of 5 gallons or more, to be shipped in our 5-gallon cans for shipping honey, \$1.00 per gallon, package included; 10 gallons, 5 per cent off; 100 gallons, 10 per cent off. Samples of both will be mailed free of charge on application. Each can will have our label, and the label of the owner of the sugar-bush where it was made. As each man is anxious to build up a trade on the quality of his syrup, they are all going to try hard to see who can furnish the best. We have also in stock

FINE MAPLE SUGAR,

Put up in four grades—7, 8, 9, and 10 cts. per lb. In boxes of about 50 lbs., $\frac{1}{2}$ cent less than the above prices; in barrels of about 250 lbs., one cent less than the above prices.

A NEW BOOK ON MARKET-GARDENING.

W. W. RAWSON, of Arlington, Mass., has just put out a nice little book, "Success in Market-Gardening, and Vegetable-Grower's Manual." It is a book of 208 pages, and very fully illustrated. You will remember, that it was Mr. Rawson's establishment I visited last summer. While quite a portion of the book is, in many respects, similar to Peter Henderson's Gardening for Profit, there is a good deal in it that has never appeared in any other work. For instance, Mr. Rawson is the first man of whom I know who has made irrigation a success and a paying investment, in the Eastern States. He is truly a market-gardener on a large scale, and probably has more capital invested in the business, and sends a larger product to market, than any other one man in the world. The book ought to be worth all it costs, to any one in the business, no matter how well he may be posted, because it enables him to compare these methods and results with his own.

The price is only \$1.00, postpaid, by mail. If wanted by freight or express, we can furnish it for an even 90 cents. The work is exceedingly practical. Mr. Rawson tells us what he has done and what he is doing, and not a rehearsal of matter already to be found in other books. There is nothing in the book that has been copied from other writers.

CIRCULARS RECEIVED.

The following price lists have been received at this office:

- Will Ellis, St. David's, Ont., Can. Samples of nice fdn.
- F. F. Graves, Waterville, Me. A 9 page list of bee supplies.
- M. S. J. M. Reuter, Columbus, Neb. A 4 page list of bees and queens.
- E. M. Yeomans, And-over, Ct. A 5-page price list of bees and queens.
- C. W. Costellow, Waterbury, Me. A 11 page circular of bee supplies.
- R. P. Small, Danham, Pa. An advertising sheet of apianian supplies.
- M. J. Dickason, Hiawatha, Kan. An 18-page list of apianian supplies.
- B. J. Miller & Co., Nappanee, Ind. A 16-page list of apianian supplies.
- Reynolds Bros., Williamsburg, Ind. A 16-page list of bee-supplies.
- S. B. McLean, Columbia, Tenn. An advertising sheet of bees and queens.
- T. F. Shepherd, Franklin, Pa. A 4-page (large size) list of bee-supplies.
- Arthur A. Davis, Clark's Green, Pa. A 12-page circular of bee-supplies, queens, etc.
- Geo. W. Drinn, Laurelville, Hocking Co., O. An 8-page list of bees, sections, etc.
- N. B. Peasall, Morris, N. Y. A 20-page (large size) circular of seeds, plants, poultry, and bee-supplies.
- F. D. Welcome, Mechanic Falls, Me. A 16-page (large size) circular of bee-supplies and small fruits.
- Jos. E. Shaver, North River, Va. A 30-page circular of bee-hives, foundation, and supplies in general.
- Abbott Bros., Southall, London, England. An 8-page circular of all tools necessary for making hives, supers, etc.
- G. W. Stanley, Wyoming, N. Y. A 12-page list of the Stanley Automatic honey-extractor, giving testimonials, etc.
- B. Davidson, Cuyahoga, Ontario, Canada. A 4-page (large size) list of hives, section boxes, comb foundation, etc.
- J. W. Eckman, Richmond, Texas. A very pretty price list, folded in the form of an envelope. Bees, queens, poultry, etc.
- E. S. Armstrong, Jerseyville, Ill. A 34 page circular of Armstrong's reversing hives and reversing section boxes; also of bee-supplies in general.
- W. W. Bliss, Duarte, Los Angeles Co., Cal. A 10-page price list of apianian supplies. As he is located on the extreme Western coast, he will probably receive a large share of the Western trade.
- Aspinwall & Trendwell, Barrytown-on-Hudson, N. Y. A 34-page (large size) list of bee-keepers' supplies. Our friends A. & T. are the editors of "The Bee-Keeper's Magazine," published at the address above.
- Thomas B. Blow, Welton, Herts, Eng. A 60-page price list of everything most useful for the apianian. This catalogue gives us quite an idea of the preferences of the English people in supers, hives, and frames. Next to the Abbots, we believe that Mr. Blow is the largest supply-dealer in England.
- W. T. Falconer, Jamestown, N. Y. A 20-page (large size), neatly gotten-up circular of bee-supplies. Friend Falconer offers quite a large collection of implements for the apianian, and some new styles of hives, supers, etc. Although he is one of our strongest competitors in the supply-business, we take pleasure in recommending him to our bee-friends as a nice man to deal with.
- W. P. Davis, Goodman, N. C. A 6-page list of bee-supplies.
- Levering Bros., Wiotia, Iowa. A 8 page list of bee-supplies. The two last mentioned were printed at this office.

CONVENTION NOTICES.

Bee-keepers are hereby notified that the annual meeting of the Stark Co. Bee-keepers' Society will occur on April 12th next, in Grange Hall (over Farmers' Bank), Canton, O. Officers for the ensuing year will be elected. All bee-keepers are urged to be present and those having hives or fixtures are requested to bring the same for exhibition. MARK THOMSON, Sec.

CALIFORNIA APIARIES.

We have four apiaries for sale, varying in price from \$500 to \$1000. For detailed information write to
FORTH, EASLEY & REPPY, Agts.,
San Buenaventura, Cal.

FOR SALE.—A complete apiary of 140 colonies of fine premium bees in a never-failing locality. A bargain, if called for soon. My bees and queens were awarded first premium at the late St. Louis Fair. St. Louis, Mo. Address at once.
L. WERNER, Edwardsville, Ill. 4tfab

WANTED.—A steady man to work small apiary and garden. Correspond with J. T. DUEWALD, Seneca, Wis.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column. 3btfcd

KIND WORDS FROM OUR CUSTOMERS.

THAT WHEELBARROW.

The wheelbarrow is excellent, and goes beyond my expectations. C. K. DECKER.
Hanford, Cal., Jan. 22, 1887.

RUBBER STAMPS.

You will see by this card that we have received our rubber stamp, and are well pleased with it—the handiest thing we have got hold of for some time. LaSalle, Ill. T. & B. YOUNG.

I am well pleased with GLEANINGS, and I do not think I can do without it. It is much company to me. As there are so many good Christian friends who contribute to its pages, it is like conversing with dear friends I have known. N. A. E. ELLIS.
Astoria, Mo., Jan. 5, 1887.

OUR NEW REVERSIBLE FRAME, AND HOW IT PLEASES.

Please send me the price of 500 wired reversible frames, L. size, put together, ready for the fdn. I have 250 now in use, and I like them better than any other frame I ever used. J. G. NORTON.
Macomb, Ill., Feb. 4, 1887.

I have enjoyed reading the few copies of GLEANINGS I ordered with my bill of notions last fall so much that I think I shall be able to read it the coming year or will subscribe for it. I "glean" a great deal from it. D. C. AYERS.
Moawequa, Ill., Dec. 3, 1886.

HOW THE A B C BRINGS ABOUT SUCCESS.

I must say that I have derived such a vast amount of good from the A B C that I am astonished myself to think what a powerful thing is knowledge. I have followed your directions, and have succeeded. I have a splendid honey-crop, if I may call it a crop. A. H. BAUM.
Ashland, Ohio.

AN IMPORTED QUEEN IN HER THIRD YEAR, AND STILL DOING GOOD SERVICE.

I had, Oct. 1, the imported queen I got from you in May, 1884. You said she was imported the year before. She has been a very prolific queen, and has given my bees lots of "vim," or vigor, and was well worth the price paid. She has kept her hive full of bees this season. She looked rather old the first of October. G. W. GILLET.
Wellington, O., Nov. 24, 1886.

DON'T KNOW HOW TO GET ALONG WITHOUT IT.

Since writing to you to stop my journal I have repented, and don't know how to get along without it, so here I send a dollar, for which to renew my subscription. I just want to say, that I appreciate your kind words of counsel and instruction very much. I have learned much in your journal that has done me good. I wish you success in the good work. W. M. SENFF.
Bremen, Ind., Dec. 31, 1886.

I consider GLEANINGS the best bee-journal I know of, and I could not well keep house (or bees) without it; neither is the attractiveness impaired by the work done under the head of "Our Own Apiary." A host of A B C scholars are being added to your list each year, and these topics that were ventilated a few years ago are new to them, and they are anxious for these facts. S. S. LAWING, P. M.
Henderson, Mo.

THAT A B C BOOK ON TRANSFERRING.

Friend Root, let me tell you how I have got acquainted with bees and your valuable books. Last August a friend invited me to see his bees. I visited him, and he opened one of his hives, showed how it worked, and explained to me all about it. He gave me one of your catalogues. I went home and got so interested in the matter that my mind is wholly taken up with bees. I then sent immediately for the A B C, which I have been reading all the time. I went to work and got 12 swarms in box-hives. Following my A B C book in transferring, I transferred one late in September in less than half an hour, without smoke, gloves, or veil.

Brooklyn, N. Y.

ANTON KIRSCH.

THE A B C OF CARP CULTURE.

The A B C of Carp Culture came to hand all right. I think it is 40 cts. well invested. When I go home to Michigan for the purpose of occupying my land in that State I expect to start an apiary, and will construct ponds, and get them well started with water-plants, preparatory to receiving the carp for propagation. A. RICHMOND.
Keenansville, Ont., Nov. 29, 1886.

SECRETARY CHAMBERLAIN'S OPINION OF TERRY'S POTATO CULTURE AND WINTER CARE OF HORSES AND CATTLE.

I have Terry's potato-growing, the best thing ever printed on the subject, in my opinion. I may say the same of his work on cattle-feeding, which he wrote (in substance) at my request, and gave at many institutes as a lecture. W. I. CHAMBERLAIN.
Ames, Ia., Jan. 31, 1887.

THE KITE FOR LITTLE ONES.

You said, as I subscribed in October I was hardly entitled to a kite; but you sent it, as perhaps it would gladden some young heart. It did gladden a young heart. The owner of the kite is six years old, and calls me papa. I thank God that A. I. Root has such kind-hearted Christians in his employ, to have such sympathy for our little children as you manifest in your card. L. H. WILCOX.
Farmington, W. Va., Nov. 23, 1886.

A KIND WORD FROM MRS. HARRISON IN REGARD TO OUR A B C BOOK ON CARP, AND ALSO FOR OUR POTATO-BOOK.

Please accept my thanks for your giving to the world, in cheap form, two such excellent works as the A B C on Carp, and on Potato Culture. I do not expect to engage in the culture of either, but I think their perusal paid me well. If they had cost a dollar apiece, I should not have enjoyed the treat. 821 Hurlburt St., Peoria, Ill. MRS. L. HARRISON.

THE STORY OF THE BIBLE, AND WHAT OUR OLD FRIEND WM. MUTH-RASMUSSEN THINKS OF IT.

Please send me by mail 6 copies of the "Story of the Bible." These are for the Sunday-school of which I am superintendent. I think they will be easier to learn and understand, than the common lesson-papers. I have not been able to see all the parents yet, and may therefore get orders for more books. W. M. MUTH-RASMUSSEN.
Independence, Cal.

OUR NEW FLAT-BOTTOMED FOUNDATION.

Your sample of flat-bottom fdn. is at hand, and is very nice. Could you tell me about how many pounds of the flat-bottomed would be required to fill full 1000 sections, 4 1/2 x 4 1/2? The 5000 Simplicity sections are the nicest I ever bought.

17—J. M. BROOKS—57.
Columbus, Ind., Feb. 11, 1887.

[One sq. ft. is enough to fill 10 sections. You would need, for 1000 sections, 100 sq. ft.; and as this flat-bottomed fdn. goes over 14 ft. to the lb., you would need about 7 lbs. to the 1000 sections.]

EVERY THING SATISFACTORY.

I received my goods all right, for they were packed so neatly for shipping. My wax-extractor I am more than pleased with, for it is a little daisy. My comb foundation is as nice as I ever saw. You had my A B C book packed so well it would have carried 1000 miles as well as the distance it did ride. I would not take double for my book what I paid for it, and do without it, for it is a perfect guide to bee-keeping. Your book is so cheap that every bee-keeper ought to have one. JOHN H. PENCE.
Terre Haute, O., Dec. 3, 1886.

THE A B C AND THOSE SERMONS.

Inclosed find \$1.00 for GLEANINGS. About one year ago, becoming interested in bees, I accidentally got one of your price lists in my hands, and forthwith sent you an order for an outfit in bee culture. Since then I have ordered of you at various times, and am glad to say that my orders were promptly and satisfactorily attended to. By the advice and light of your A B C book I have gained much theoretical knowledge which has enabled me to put into successful practice many of the seemingly gigantic operations connected with bee-

keeping. My 8 colonies are wintering on their summer stands, with no protection except a chaff cushion placed over the frames, and all seem to be all right. Every few days it is warm enough for them to come out and air themselves, and I assure you they seem to enjoy it. I very much enjoy working with and for the little rascals, but not half so much as I do reading those "sermons" of yours in GLEANINGS. These, only, caused me to subscribe at first, and to renew now. May you live long to shed life on the Christian pathway, and turn souls from dark and deceptive ways that lead to ruin.

D. C. McCAMPBELL, M. D.
Harmontown, Miss., Jan. 18, 1887.

A KIND WORD FOR OUR MAPLE SYRUP.

The sample of maple syrup came all right. I must say it is the finest I have tasted in twenty years; and, besides, only 20 cts. more per gallon than is asked for the best sorghum here. I intend to send for some of it in a few weeks. It is my favorite syrup, and I could drink it as others drink wine, but of course I would not. I have only one colony of bees left in Utica, Mo. I took sixty pounds of surplus honey from it last summer.

Quincy, Ill., Mar. 10, 1887. Mrs. S. C. TYLER.

"BEARING OUR SHARE OF SUFFERING."

I am anxious to tell you how much I enjoy reading GLEANINGS, or hearing it read. The way you wrote about bearing our share of suffering caused me to think, as I had never thought before. I had been blind with sore eyes for about four weeks, and the thought of being compelled to give up taking care of the bees was hard to bear; but it has pleased our kind heavenly Father to restore my sight, although my eyes are not strong. I shall try to procure some subscribers for GLEANINGS. It ought to be in the home of every bee-keeper at least. The bees did not store much surplus honey the past season.

J. T. VANPETTEN.
Linn, Kans.

A PLEASED CUSTOMER.

The goods were received in tiptop order. The soldering implements are worth their weight in gold. I would not take \$5.00 for them, if I could not get some like them. The glass-cutters speak for themselves. I can not see how you can offer them for so small an amount of money. They are worth to me 25 cts. apiece. The 3 cts. in stamps, which I received for discount, I did not expect when I sent you the order. I could have saved you some trouble if I had thought of it sooner. I think your journal worth the money any time. I could not do without it, and the A B C book is a splendid book. I have gained many a practical hint out of it. The bees in this part of the country are in good condition so far. The goods were only three days in transit. Freight charges were reasonable. Many thanks to you.

H. D. FRIEND.
Douglas, O., Feb. 24, 1887.

[Well, friend F., you are a "friend" indeed, in more senses than one. I feel almost guilty about letting such a very kind letter go into print, for some one will accuse us of picking out only the kind words and not printing the others, and we surely ought to be consistent as well as truthful, therefore we put in something to balance it in the department of Growlery, which see.]

THE HOME TALKS.

Bro. Root—(for I do feel that you are indeed a brother in Christ), every time GLEANINGS comes to hand and I read Myself and Neighbors, also Our Homes, it fills my very soul to overflowing with love and gratitude toward you—so much so that it seems at times I have almost got you by the hand, giving it a welcome shake. Do not think that I am trying to flatter you—far from it. When I read the good advice you give to Christians in the way of discharging our duty in order to bring sinners to Christ, it has made me set a more determined resolution to live closer to the Savior, and let my light shine brighter, that I may yet, in my old age, be the means of saving some poor souls by my godly walk and conversation. I have just finished reading Myself and Neighbors and Our Homes of the 15th of Dec., and it fills my soul with joy to think there is a man in my native State of Ohio doing the good that I am satisfied you are doing, for I know you have done me good in many ways. I have been thinking about dropping GLEANINGS for a year, and taking

another journal; but after reading what I have just read, I do not see how I can give the good old GLEANINGS up for any thing else. But should I give it up for a while, I shall not give up A. I. Root or any thing in his line of business, or of teaching the ways of the blessed Redeemer. May God help you to continue in the good work you are in, is the prayer of one who loves you.

CHAS. L. GOUGH.
Rock Spring, Mo., Dec. 22, 1886.

[My dear friend and brother, you are certainly giving me more credit than I deserve. You have perhaps seen only my best side. If I have been so fortunate as to show forth the spirit of the Master now and then, let him have all the honor and praise and glory; and do not, I beseech of you, place too much dependence on any thing human. You know we are but dust, even the best of us.]

HOW THE A B C CAME TO THE RESCUE IN WINTER-ING.

I bought an A B C book and 14 colonies of bees late in the autumn of 1884. Not having any smoker, and being a novice, I can assure you I had a lively time preparing them for winter. They were in a starving condition. I fed syrup from granulated sugar; but it became so cold, before they had taken up sufficient stores to winter upon, that they would not lick it up. I searched my A B C and found a remedy in cakes of sugar like marble which I made 2 inches thick, in frames, placing them over the racks, and covering with chaff cushions. I clamped them according to instructions in the A B C, and I can tell you, friend Root, they hibernated in good style, although that was the very severe winter in which some of our old beemen lost so heavily. I lost but one colony, and I believe it had been queenless early in the fall.

I shade the entrances of the hives, or front of the clamps, which are 24 feet long, with a shanty roof of boards, putting air-tubes at each end, allowing the snow to cover over the whole fabric, keeping air-tubes open except in the severest weather, when I stuff them with straw. During the summer of 1885 I increased to 34, which I wintered without any loss. They were just booming in the spring. I had 8 large swarms in May (don't forget we are pretty far north of you). I feel grateful to you, friend Root, as my success so far is largely due to A B C and GLEANINGS.

J. H. REED.
Mimosa, Ont., Can., Jan. 27, 1887.

HOW OUR GOODS PLEASE IN AUSTRALIA; "GOOD VALUE FOR THE MONEY."

The goods I ordered of you arrived here Oct. 11th in good order; and to say that I am pleased with them is not sufficient to express the gratification I experienced when I found what really good value I had received for my money. I may say, I have been working machines in sawmills for the last 20 years; and the only wonder to me is that you can supply such finished goods at such a low price. I also received from you last mail the parcels of books. I am sure you must feel gratified at knowing that your A B C of Bee Culture is becoming more appreciated in this colony. I now have orders for three more, but I tell them they must wait till I can get them over by freight. I intend to send from here in the December mail a good large order for hives and appliances, so that I can get them in time for next season. The hives you sent I could have sold, but I wanted some myself, so I kept half of them. It's rather amusing to think that three years I was reckoned a lunatic; two years ago people fancied I was not quite foolish; one year ago they wanted to know how I managed to get so much honey, and this year the district is getting the fever very badly, so I think I shall be able to start a supply-business.

I wrote you previously, that I ordered eight queens from Chas. Bianconcini, of Bologna, Italy, through seeing his advertisement in GLEANINGS. I received the queens on the 21st of Oct., all alive, and have them introduced and laying. It was 42 days from the time they left his place. He had evidently given them every attention in packing. Allow me again to express my pleasure in doing business with one who evidently practices what he preaches.

The foundation-mill works well. By following your directions I had no trouble at all, but I can not manage to get sheets of wax 3 ft. long; but that will come by practice.

Also B. Leghorns, P. Rocks, and Raspberries.
5-6-7d □ Box 34. J. W. CLARK, Clarksburg, Mo.

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 5 lines, and you must say you want your ad in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. Of course, this department is intended only for bona-fide exchanges.

WANTED.—To exchange for good horses and mules, 200 colonies of bees in Simplicity frames; also 40 acres of land adjoining the city.
20-ftdb ANTHONY OPP, Helena, Phillips Co., Ark.

WANTED.—To exchange eggs from four yards, pure-bred prize-winning Plymouth Rocks, for alsike clover seed. Eggs, \$2.00 for 13, or \$3.00 for 30.
B. D. SIDWELL,
3-8db Flushing, Belmont Co., Ohio.

EGGS for hatching.—Wyandottes, Polands, Hamburgs, and Leghorns, in exchange for section boxes, or foundation. Circulars free.
4ftdb. A. H. DUFF, Creighton, Ohio.

WANTED.—To exchange nursery stock of all kinds for bees in spring. Terms on application, stating what you want.
D. G. EDMISTON,
4ftdb. Adrian, Mich.

WANTED.—To exchange 40 acres of good land, $\frac{3}{4}$ improved, frame house and barn, good spring, $\frac{3}{4}$ mile from a thriving temperance town; good schools, church, etc., and situated on the great basswood belt of Wisconsin, for property in Arkansas, small or large. Apiary if desired. Correspondence solicited.
M. A. GILL,
5ftdb Star, Vernon Co., Wis.

WANTED.—To exchange for bees, or offers, 160 acres of Western Neb. land, 160 acres Central Kan. land, 80 acre Western Iowa farm. Immediately, if at all.
ANTHONY JOHNSON,
5ftdb Essex, Page Co., Iowa.

WANTED.—To exchange for comb honey, one dovetailing machine, 8 saws, steel mandrel, and table; good as new. Root's pattern. For particulars address
B. F. STOVER,
6d Roscoe, Cosh. Co., O.

WANTED.—To exchange, any amount of Wyandotte and Brown Leghorn eggs for grapevines, fdn., plum-trees, or any thing useful.
6-7d BENJ. ZURCHES, Apple Creek, Wayne Co., O.

WANTED.—To exchange for sewing-machine, Brown Leghorn pullets, 75c; cockerels, \$1.00; eggs, 75c per 13; 26, \$1.00. Warranted pure.
6-7d MRS. ALICE BRIGHT, Mazeppa, Minn.

WANTED.—To exchange Italian bees and queens for S. S. Hamburgs and White Leghorns and other poultry and eggs. None but the very finest stock wanted. Also your address wanted for my new circular.
CHAS. D. DUVAL,
6d Spencerville, Montgomery Co., Md.

WANTED.—To exchange a new Hitchcock's Bible, cost \$9.75; Sharpless, Crescent, Monarch, and Wilson Strawberry-plants, for pure Italian queens, also pair of Plymouth Rocks.
S. J. ADAMS,
6d Cub Creek, Charlotte Co., Va.

WANTED.—To exchange forty thousand extra-fine Cuthbert, Gregg, and 13 other new varieties red and black raspberry plants, for comb or extracted honey. The honey is to be delivered next fall. Write for terms of exchange to
E. T. FLANAGAN, box 995,
6-7-8d Belleville, St. Clair Co., Ill.

WANTED.—To exchange pure-bred S. C. Brown Leghorn hens for white Leghorn; will also exchange eggs from the following varieties: Light Brahmas, Dark Brahmas, Plymouth Rocks, Brown Leghorns, S. S. Hamburgs, P. Ducks, Bronze Turkeys, for eggs of white Wyandottes and White Plymouth Rocks. I will warrant all fowls to be purely bred, and all right. Prices reasonable.
6d Send for circular. B. J. PURCELL, Concord, Ky.

WANTED.—To exchange bees by the pound or full colonies, queens, comb fdn., eggs for hatching from L. Brahmas and S. S. Hamburgs, for sections, Jersey cow, American Merino sheep, or offers.
6-7-8-9d J. P. STERRITT, Sheakleyville,
Mercer Co., Pa.

WANTED.—To exchange eggs from pure-bred Langshan fowls, for beeswax, tested Italian queens, good revolver, or any thing useful.
6d E. P. ALDREDGE, Franklin Square, Col. Co., O.

WANTED.—To exchange fine colonies of Italian bees in splendid double-wall hives, for good silver watch. Write immediately to
M. J. HARRIS, Clay City, Clay Co., Ill.

WANTED.—To exchange untested and tested Italian queens, for sections, tested H. L. queen, Pelham fdn. mill, or offers. Address
6d B. L. BOURLAND, Valley Spring, Texas.

WANTED.—To exchange Italian or Albino bees and queens, for a good gold watch (it must be a very extra good time-keeper), or a double-barrel breech-loading shot-gun, or for something else that is valuable. Address
OTTO KLEINOW,
6d (Opp. Fort Wayne Gate), Detroit, Mich.

WANTED.—To exchange for beeswax, one foot-power saw. Also wanted, a good Mexican saddle and bridle, for sections or other supplies.
6-7d C. A. GRAVES, Birmingham, Ohio.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is often times quite an accommodation to those who can not afford higher-priced ones.

Six or eight hybrid Italian queens at 50c each,—to be mailed in March. During April I can supply 9 or 10 pure black, or German queens, which I shall obtain in Italianizing for a friend, at 30c each. Safe arrival in all cases.

ABBOTT L. SWINSON, Apiarist,
Goldboro, Wayne Co., N. C.

W. Z. HUTCHINSON,
ROGERSVILLE, GENESEE CO., MICH.,

Has written, published, and now offers for sale, a little book upon "THE PRODUCTION OF COMB HONEY." Although its distinctive feature is that of teaching how to profitably dispense with full sheets of foundation in the brood-nest when hiving swarms, several other points are touched upon, and the system of comb-honey production that the author believes to be best is briefly outlined. Price of the book, postpaid, 25 cts. 7tdb

HONEY COLUMN.

CITY MARKETS.

CINCINNATI.—Honey.—There is a fair, reasonable demand for table-honey in small packages, and demand from manufacturers is better than it has been. We quote 11@14 as the range of prices for best comb honey in the jobbing way, and 3@7 for extracted honey on arrival.

Beeswax.—There is a good demand for this, which brings 20@23 on arrival for good to choice yellow.

Mar. 23, 1887. CHAS. F. MUTH & SON,
Cincinnati, Ohio.

CHICAGO.—Honey.—The market is without material change. There is no outside demand for honey of any kind, and sales here are from hand to mouth. Prices are weak. Buyers of any quantity could get liberal concessions from figures in previous quotations.

Mar. 22, 1887. R. A. BURNETT,
161 So. Water St., Chicago, Ill.

DETROIT.—Honey.—The market continues same as last quoted; viz., 10@11 for best white comb honey.

Beeswax, firm, with a little more inquiry, at 23c.
Mar. 22, 1887. M. H. HUNT,
Bell Branch, Mich.

ST. LOUIS.—Honey.—We have nothing new to report. Our honey-market is still overstocked, and the reduction in price does not seem to encourage dealers to take hold. Quotations same as last.

Mar. 22, 1887. W. B. WESTCOTT & Co.,
108 and 110 Market St.

KANSAS CITY.—Honey.—We quote white-clover, 1-lb., 11@12. No change in 1-lb. dark, or 2-lb. white or dark; extracted, white clover, 5@5½; dark, 4@5; white sage, extracted, 5@5½; amber, 4@5.

Beeswax, 23@25. Market slow.
Mar. 22, 1887. CLEMONS, CLOON & Co.,
Cor. Fourth and Walnut Sts., Kansas City, Mo.

CLEVELAND.—Honey.—There is no change in our market. Best 1-lb. white sells at 13; 2-lb., 10@11. Second quality, 1-lb., 9@10. Extracted, dull at 5@6.

Beeswax, 25c.
Mar. 22, 1887. A. C. KENDEL,
115 Ontario St., Cleveland, O.

BOSTON.—Honey.—We have no change to make in prices. Our sales have been fair, considering the extremely cold and stormy weather we have had the past month.

Mar. 23, 1887. BLAKE & RIPLEY,
57 Chatham St., Boston, Mass.

PHILADELPHIA.—Honey.—The season is over for honey.

Beeswax sells right along, however; 20 to 30 as to quality.

Mar. 22, 1887. PANCOAST & GRIFFITHS,
242 South Front St., Philadelphia.

NEW YORK.—Honey.—No fancy white honey in our market whatever, and we now have a fair demand for lower grades. We quote:

Fair white, 2-lb. sections, glassed	-	-	-	8c

Mar. 22, 1887. THURBER, WHYLAND & Co.,
New York.

FOR SALE.—About 300 lbs. of buckwheat and fall honey in 1-lb. boxes, at 6 cts. per lb.

WM. VANAUKEN,
Woodville, Jefferson Co., N. Y.

FOR SALE.—500 lbs. of nice white-clover comb honey in 1-lb. sections. Will ship in 48-lb crates at 13 cts. per lb., or crates returned at 12½ cts. per lb.

B. F. FOUST,
Fredricksburg, Wayne Co., O.

For Sale. Full Colonies of Italian Bees, 2, 3, and 4 Frame Nuclei.

Tested queens before June 1st, \$1.50 each; after, \$1.25 each. Untested, before June 15th, \$1.00 each. After that date, single queen, 75 cts.; six for \$4; twelve for \$7.75. Pounds of bees, same price as untested queen.

7tfdb I. R. COOD, Nappanee, Ind.

FRED'K HOLTKE

Offers 15 Choice Varieties of Greenhouse Plants for Only \$1.00!

Such as Geraniums, Fuschias, Pansy, Daisy, Alyssums, Primula, Roses, Begonia, etc. All plants will be sent by express unless otherwise ordered, as I can send larger and finer plants this way than by mail. I will send enough **EXTRAS** to cover express charges. If wanted by mail, add 25 cts. for postage, etc. As a **PREMIUM**, I will send one packet of Peter Henderson's choice mixed Victoria Aster seed, something very fine. Satisfaction guaranteed. Nuclei, with untested queens, later on.

6tfdb Carlstadt, Bergen Co., N. J.

KANSAS.

COMB FOUNDATION, AND OTHER SUPPLIES FOR THE APIARY.

PRICE LIST FREE. Address

THE ORIGIN OF THE T TINS.

A FEW MORE SUGGESTIONS FROM DR. MILLER.

ON page 216, GLEANINGS, Mr. Heddon presumes I can tell where removable T tins were formerly mentioned in one of our journals. The first mention of them that I remember in print is that of which I speak on page 39, "A Year Among the Bees," and is in the *A. B. J.* for 1884, page 133. Mr. C. H. Dibbern there gives a description, I think his own invention. They were undoubtedly invented before this, although Mr. Dibbern probably knew nothing of it. I think Mr. D. A. Jones mentioned them at Cincinnati in 1882, but I may be mistaken. In 1883, at Toronto, Mr. Jones showed me a T super, from which I got the idea. This super had the bee-space at the bottom, and the T tins were supported by square strips of wood, perhaps about $\frac{3}{4} \times \frac{1}{2}$, running around the entire inside edge of the super. This allowed T tins to be placed at any point, and also allowed T tins of different lengths to run the long way of the super. To Mr. Heddon I give the credit of the slat honey-board, and I think I would almost go back to wide frames if I had to give up the slat honey-board.

I want to heartily thank Mr. Wm. Drew for calling attention, on page 217, to an inexcusable blunder of mine. I had mentioned that T tins could be used over as well as under the sections; and my idea was, that the same size of tins would do. But a little figuring will show, as Mr. Drew has done, that to use T tins at top and bottom, with $3\frac{1}{2}$ -inch separators, they must not be more than $\frac{3}{8}$ inch deep. I think he may be right, that $\frac{3}{8}$ inch is sufficiently strong; and if so, I see no good reason for making them larger. They can then be used over as well as under the sections. Until the matter is put to

actual test I think we had better not be in great haste to decide that we want any T tins on top. There is no very serious difficulty without them. The sides of a few of the sections are badly daubed with propolis, but most of them are quite free, and the tops are very clean. The bottoms of the sections have a line of glue along the edge of the tin; and if T tins are used over the sections I presume the tops of the sections would be marked the same way. As I have used them (without T tins on top), the tops of the sections look much nicer than the bottoms; and as the top of a section is the part that shows most, I think I would rather have the glue on the sides than to have the top like the bottom. So, although I show my fickleness in so doing, I must advise against T tins on top. Possibly we can gain all the advantages we want in an easier way. If T tins are put on above, I see no use for the side wings, for they support nothing. So take merely a straight piece of sheet iron or heavy tin of proper length, and $\frac{1}{4}$ or $\frac{3}{8}$ inch wide, as the case may require, and we have all the advantage of the T tins without the glue-line. The objection that friend Drew makes, that the last T tin (or straight tin) is difficult to insert, does not hold good with my supers, $17\frac{3}{4}$ inside length. I have just tried it, and they go in quite easily. With only $17\frac{1}{4}$ inside length there may be more trouble, as also in putting in the sections.

Your plan, friend Root, of nailing on the six little pieces of iron at the factory is undoubtedly good—better, perhaps, than you think; for when you have every thing ready you can nail on a great many pieces while the purchaser would be getting ready to nail on the first piece.

I don't suppose I shall ever use an outside shell over my supers (yet I've changed so many times it

is not safe to predict what I will or will not do), but I confess you have the better of the argument; and so long as you can conveniently do so, it may be best for you to make use of the outside shell. But if I must suffer the chagrin of giving up in this, I can twit you of omitting an argument—that your supers are lighter. I count this a matter of considerable importance; for where you are handling these supers all day long, a difference of a pound or more in weight may make quite a difference in the amount of ache you feel at night at your backbone. Please don't come down too hard on me if I should hereafter get to using outside shells

AN ADVERTISEMENT.

I know advertisements are not admitted in the regular reading-columns, but I am in hopes Mr. Root will not notice this one till the printer gets it too far along. I want to advertise that I have no bees to sell, no queens to sell, no hives, no supers, *no nothing* in the way of supplies of any kind, and I hope the friends will save the trouble of writing to me for prices. I am nothing but a bee-keeper, pure and simple. This for two reasons: First, I don't know that I should be successful in doing things satisfactorily, and I love my ease too well to want to be worried over it. Second, if the queen-dealers, the supply-dealers, and the bee-papers, have any right to exist it is because they have a basis in honey-raising as a business that may be desirable and profitable. So I settle on the line that honey-raising is my business.

For one, I want to thank you, friend Root, for your words so kindly spoken of your most formidable rival. The longer I know Bro. Newman, and the more I know about him, the more I think he is a man who has the good of bee-keepers at heart, and whom we should sadly miss out of his place.

Marengo, Ill., Mar. 21, 1886.

C. C. MILLER.

HALF-POUND SECTIONS.

CROWDING BROOD-FRAMES TOGETHER.

I MADE some experiments last season in cutting the 1-lb. boxes in two—that is, cut crosswise, so as to be $2\frac{1}{2}$ inches in depth for holding $\frac{1}{2}$ lb., or about. Theory told me bees would not accept them as readily as full size, and they did not quite; but I do think the plan will work, as consumers will buy a $\frac{1}{2}$ -lb. box when they wouldn't more. These small sections, too, look very cunning and neat. My plan was to use whole boxes on the outside, all filled with fdn. I used separators; and as I use only a 20-lb. case I got very even and full sections. I use and make a side-opening case, with no glass sides, which tend to keep bees out of the outside sections, and, besides, costs more. I am so well pleased with the little sections that I shall use many this season. I also used $1\frac{1}{2}$ -inch sections, full size, $\frac{3}{4}$. I believe they are sure to get the bees at work sooner than a wider box, and can be used quite well without separators. But one great reason for the use of separators is, we can feel sure of even combs, and can remove a single box and insert one with fdn., or exchange outside for the center, and all is well. But when we use $1\frac{1}{2}$ -inch-wide box the case is different, as the bees, of course, are closer, and the combs are nearer to each other; and with only 24 boxes of the narrow ones, separators are not so much needed. One thing is sure to pay;

and that is, to use full starters, or to fill within $\frac{1}{4}$ inch of the bottom of the section.

How one can get along and use only starters in brood-frames, I never could see. I am always getting drone brood in such, yet perhaps a whole hive of starters would come out all right.

A great many ways to get bees into the surplus department have been given. I well remember how the thought of crowding the combs close together flashed through my mind some time in the month of August, four years ago. It was a little late, but I tested it as best I could at that time. The next spring I made a thorough test, as reason told me it would work. I had noticed, when extracting, as I naturally closed combs quite near, that the queen would lay nearer the top than usual; and upon a second thought I said to myself, "Keep them thus, and the bees can't bulge them, and Mrs. Queen will use it, as she uses only $\frac{1}{2}$ comb for workers." The idea was in harmony with her duty. I wrote an article on it for the *Lewiston Journal* that season. I had never heard or read of any such plan, and I was reading four bee-journals and four newspapers. I was and am so well pleased that I make all my frames with half-closed ends, so as to allow only a bee-space. Some would object to frames at fixed distances, but the advantages are to me a great deal more than inconveniences, of loose, uneven combs and frames.

E. P. CHURCHILL.

Halowell, Maine, Mar., 1887.

EMPTYING THE T SUPER.

DR. MILLER SHOWS HOW IT IS DONE.

AS some of our correspondents fail to understand the device and the method of emptying the T super, as described by Dr. C. C. Miller in his book, we wrote to him asking him to get every thing in readiness and put himself in an attitude for emptying the T super. He was then to have his photographer take a view. Friend Miller did as we requested, and, as you will see, has sent us a photograph illustrating the manner of emptying. Along with the photograph he sent the following explanation:

Friend Root:—I have mailed you to-day a photo of myself in the act of taking out a super of sections. The hat on the table is one of my five-cent hats with veil attached. Beside it is a full super. Next is a mallet, roughly padded (it was originally made to jar curculios off plum-trees), to hammer on the upper edge of the super, as explained on p. 91, "A Year Among the Bees." In the book I used a heavy hatchet, or hand-ax, but I like this padded mallet better. On top of the two empty supers at my side lies a stiff case-knife, used to cut through the propolis which may fasten the upper part of the sections to the super. I have just pushed the super nearly half way down over the sections, and the next instant it will drop down to the bottom of the inverted hive-cover, leaving the sections clear, standing on the bearing-board. An extra bearing-board lies on the table in front of me, in which you can see the notches cut in the sides to let the sheet-iron supports of the super pass through. The pantaloons I am wearing are the ones I generally wear in my apiary work, and are Newburgh overalls, for which I paid a silver dollar.

Marengo, Ill.

C. C. MILLER.

In order that our readers may get all the facts clearly before them, we take from Dr. Miller's book, "A Year Among the Bees," page 91, two paragraphs on this subject of taking sections out of the supers.

To take out sections with this arrangement, I place it in front of me on the table—no fastening is necessary—so that the box inside the hive-cover shall be nearest to that side of the hive-cover which is next to me, and the end of the box which comes nearest the end of the hive-cover shall be at my left hand. The bearing-board is now put in place, and pushed tight in the left-hand corner. The super full of sections is placed on the bearing-board and crowded close to the left-hand corner. I now lean forward, throwing the weight of my body partly upon the super, and pressing with the left fore-arm upon the end and opposite side. Then with the closed fist of the right hand I strike upon the further corner of the super at the right hand. This breaks the attachments of the sections at this corner, and then I strike upon the different parts of the super so as to get it started all around. Then

natural look to it. From its appearance we judge that it has seen a good deal of service, and no doubt its owner considers it, ill-shapen though it be, one of the necessary adjuncts to the apiary. Furthermore, I am sure our readers will be pleased to see you with your old clothes on and in your shirt-sleeves. I had a great deal rather take a look at a friend when he is full of business, and attending to his every-day duties, than to see him all dressed up nice and slick, just as the photographer fixed him. All those who have seen Dr. Miller, I think will agree that the picture is a good one. There is nothing like having every thing arranged within arm's reach. Unnecessary steps and unnecessary movements, as is shown in another column, cost bee-keepers a good many dollars. You see, Dr. Miller has directly in front of him one of his bearing-boards

DR. MILLER, AND HIS MANNER OF EMPTYING THE T SUPER.

putting a hand on each end of the super, I push it evenly down and let it drop in the hive-cover. The bearing-board is lifted out with its load of sections, and the now empty super is also lifted out.

It is often better, perhaps always, to run a case-knife around so as to cut through the propolis that may fasten the upper part of the sections to the super. The fist will become sore if used for much pounding, so I use a heavy hatchet or hand ax. With this it is not necessary to strike heavily, whereas a light hatchet must be struck so hard that it would mar the super and not start the sections so easily. It is important to bear down upon the super while striking.

Friend Miller, you have followed our instructions to the letter. We wanted you to look just exactly as you appear when you are at work emptying the T super. Photography, assisted by good engraving, is true to life. I think we all agree, that one of the special attractions of the picture is that old hat shown on the left; it has a very

which he will place on the box inside of the hive cover, as soon as the other has been carried away with its load of sections. At his right are the supers ready to be emptied; at his left are the empty super-shells, all in arm's reach.

Now right here, Dr. Miller, I want to ask if it would not be possible for you to simplify your device for emptying the T super. Why not dispense with the hive cover? I know there is an advantage in having it, as it guides the T super so that it will come squarely on to the bearing-board without any hitching or catching. I believe you state this as a reason in your book; but is this advantage of enough importance to the bee-keepers at large for them to go to the extra expense of the hive-cover, or something similar to it, to assist in emptying a

super? If I were to make a device for emptying the T super, I believe I should make one something as follows: Get a plain board, $\frac{3}{4}$ inch thick, and just wide enough and long enough to slip down easily through your T super. I should, of course, notch it out as you do yours. I should next make a plain box, without top or bottom, 5 inches deep and $\frac{1}{2}$ inch smaller in the outside dimensions around than the bearing-board. Now, under the side of the latter I would nail two cleats. The length of each would be equal to the inside width of the box. These cleats should be nailed on this bearing-board, so that it will set on top of the box, leaving it projecting $\frac{1}{2}$ inch all around. Now, to empty the super I would place it on top of the bearing-board, being careful to get it squarely over. I should then empty the sections by crowding down the shell of the super as you do. This plan for emptying the super, I offer as a suggestion, and our readers can decide for themselves. You will notice that the only practical difference between emptying the T super as described by you and as I describe it above, is that I would dispense with the hive-cover. Perhaps the use of the latter embodies other advantages aside from the one I have mentioned.

ERNEST.

ECONOMY IN LITTLE THINGS.

ESPECIALLY ECONOMY IN LABOR.

THE one thing that confronts us just now in this age of progress is the expense of the labor required to do what we want to do. The farmer says he can not raise crops at the prices offered, and afford to keep hired help. If his boys will stay and work on the farm, he can afford to keep on farming; but when it comes to employing the average hired man, he can not do it. We meet this at every step. Many women prefer to do their own housework, because they can not afford to pay the prices for competent help, and so we are absolutely obliged to continually come back to the problem of making a little strength do a large amount of work. Just now I have one thing in this line, in mind. It is a thing I have spoken of over and over again; but I have been thinking this morning, a little despondingly, that, even if I keep on talking of it all the days of my life, there will be almost as much need of it when I get through as when I began. It is a sort of heedlessness that seems to cling to almost everybody. I do not know but careful housewives who do their own work have learned somewhat of it by sad experience; but the people I employ seem to be, a great part of them, a good deal alike in this matter. It is in preparing things convenient at hand, when we start out to do any work. The printers here in the type-room have been obliged to study this matter, for they work largely by the piece; and printers' cases have been planned with much thought and ingenuity, to save having the hand travel over even an inch of space uselessly. Go and watch a

letters he is obliged to pick up. Now, after you have watched the type-setter, go down to the garden and see the boy trimming onions for the market. Two large piles of onions lie before him. It is early in the spring, and they are small, so there is a great deal of handling necessary. Well, you will be almost sure to find him with each pile so arranged that he must change ends for each onion he picks up; and then when it is cut and peeled he must change ends with the same onion again before he lays it down. This reaching and twisting of the wrist so many times tires him, and makes his back ache, besides taking more than twice the amount of time needed to do the work. Now, it is not a big job to turn the whole pile the other end to, because he has them on a light wooden tray, and the tray could be swung around in an instant, or he could walk around and sit on the other side, then there would hardly be any need of picking up the onions at all. He can cut off the roots, peel off the outside covering, and just push them into the next pile, leaving the tops almost unmoved.

The girls who are picking over the beans, of course want three dishes—one to hold the raw material, one for the bad beans, and one for the good ones. Well, unless I get my eye right on them when they start out they will have something a great deal too large to be handy, to hold their beans—may be a half-bushel measure or a bushel-box. Then they will get these three receptacles arranged so their hands must travel a long distance to get them out of one box and put them in another. The consequence is, they are a great while longer in doing the work than is necessary; and when tired out because of these waste motions of the hands, they do not know what tired them. It is true, the one who has charge of them, and sets them at work, should fix their boxes so that the beans will have to be moved only a few inches instead of feet (just like the types in the printers' hands). But I have sometimes felt as if mankind in general objected to these easy short cuts in doing work. A woman who does her own housework, and has the care of three or four children, learns these short cuts because she is absolutely *driven* to it. I tell you, my friends, it is a good thing for us to be now and then where we are *obliged* to economize.

All over the factory and over the grounds, I continually find people doing work in the same way. One hand will be writing the name of a certain article on the outside of a package, over and over again, when the printers in the next room would print it ten times where she could write it once. Somebody who is putting goods upon shelves will get up and down for each single article, when elevating the box or basket up to a level with the shelf would enable him to do the work quickly, safely, and nicely. Farmers often do the same thing in carrying water down hill to their stock, where some sort of a cheap wooden spout could be made in an hour so as to let the water run itself. Other people will carry heavy burdens, long distances, when a little forethought might have had the commodity de-

posited almost right on the spot where it is to be used. The consequence is, a hired man or hired girl has to be called in, when a little forethought and a little looking ahead, and planning, might have saved expensive hired labor.

The worst part of it, however, is the point alluded to in the middle of this article—doing different kinds of handwork, laying pieces of bee-hives or section boxes on the table in such a way that you will be obliged to turn every piece you pick up, end for end, before you can use it, and may be doing the same thing before laying it down again. In nailing up work you not only want the right sort of hammer, and the right sort of nails, but you want a good solid bench to pound on. We have just had some cast-iron slabs made, 2 ft. long and perhaps 18 inches wide, to be laid on top of our work-benches, to pound and nail on. The slab is solid iron, one inch thick or more, and the upper surface is planed smooth and level. Now, if you want to see how much such a thing is worth, just try nailing up work on a common wooden table, and then try it by placing your work on one of these iron slabs.

The other evening Frankie was putting section boxes together with a little wooden mallet. I told him to take his basket to one of the low benches, where he could drive his work together on the iron slab, and see the difference. Why, a very light tap of his mallet sent the joint home when he would have had to pound several times on the bench where he had been working with only an inch pine board to lay his work on. Try nailing up a bee-hive by having it rest on an iron anvil, or get a huge block of stone, and make the top perfectly level and smooth. You can smooth and level the top of any stone by first getting it chipped off by a mason, then lay a slab of stone on top of it, and grind it smooth by pouring on water and rubbing it back and forth. Whenever you have any kind of work where you have to do the same thing over a hundred or a thousand times, it will pay you to spend a little time in getting every thing just as handy and convenient as it possibly can be. If you build the fire every morning in the year, have matches, kindling, shavings, firewood, a sewing-machine oil-can filled with kerosene, or whatever you use, right close at hand; but have these materials neatly put away at the same time. Now, then, when you are replenishing the supply, get enough to last.

We have a great many orders for samples of honey, maple syrup, etc. Now, if I did not almost *fight* about it, somebody would go down stairs after one bottle of maple syrup. Perhaps this person would try to fill a little bottle by pouring the syrup out of a jug. May be, before he got through some would be spilled on the floor, some on the clothes, and some on the fingers; then a cork must be hunted for the little vial; then a block of wood with a hole bored in it to put the vial in, so it can go safely by mail; then somebody must whittle a plug and have it sawed off. Then the mailing clerk must write on the block, "Sample of maple syrup." Then a piece of stout paper must be

hunted up to wrap the package in securely; then some stout string to tie the paper, and then a pair of scissors to cut off the string.

It is finally ready to be addressed; but in doing it, various utensils have been taken from their places. Some clerk is wasting time hunting for his saw, and grumbling because somebody didn't put it back. The same way with scissors, and the same way with string. Do you wish to know the remedy? I will tell you. If we shall probably need 100 samples during the season, get 100 vials just right; then 100 corks just right; then have 100 blocks of wood cut out and bored just right; stoppers to match, and blocks, are made at the same time on the turning-lathe. Some woman is then set at work at it, who has done similar work before. A combined tunnel and measure is taken from the counter store. This utensil will fill a small bottle with any liquid, without wasting a drop, for the nozzle attached to the cap will go right into the bottle. When all are put in the bottles and corked, 100 pieces of stout paper are cut exactly right; then the printer prints a label, saying, "This is a sample of — gallons of molasses that we have for sale," also giving name and address of the man who made it. One of the girls who is expert in tying up packages then ties the whole lot at once. If they are to be used soon she also puts the postage-stamp on, and they are put in a neat little basket right close to the mailing clerk. The cost of putting up the whole hundred has not exceeded 50 cents, or half a cent apiece, after the materials are all got ready. The former way it may very likely have cost 10 cts. to put up just *one* sample bottle. In other words, we have, by an outlay of 50 cts. in labor, accomplished what might have cost toward \$10.00. Now, even though you should not need more than 50 of the packages, you will make money if you never make any further use of the last 50 at all. If you look about you and see what is going on you will see this thing repeated almost every day, and, to a greater or lesser extent, in every household. Of course, you must use judgment in deciding about how many of each thing you are going to need in the course of the year, for it does not pay to have a great lot of waste material lying around; but if you make it a study, you will be astonished to find the possibility of economizing in labor by doing little things of this kind all at once, instead of going over the long laborious routine every day or every few days.

THE HONEY EXHIBITION AT THE OOLONIAL.

HOW OUR FRIENDS ACROSS THE WATER DISPLAY HONEY.

WHILE our friend James A. Abbott, of Southall, London, England, was visiting us a few months ago, among other things which he brought from his native country he showed us some fine photographs which he himself had taken with his own instrument. Mr. Abbott is a natural genius; and among his hobbies, if

I may be permitted to call them such, is photography. While at the Colonial, which took place at South Kensington, England, last October, Mr. A. secured some fine views, representing some of the choicest displays of a few of the exhibitors. Among the number of photographs which he showed us, there was one which especially attracted our attention; and as the photograph was a fine one, we concluded to have it reproduced in GLEANINGS by the Ives process, a process which imitates photography very closely. While the outline is not as clear and sharp as an ordinary wood-cut, we think the general effect is quite pretty. It gives a very excellent idea of how things must have looked in the building where the exhibits were made.

decorations; and, if we are not mistaken in what we see in the picture, they even had tropical plants interspersed here and there. On the right are two globes, which we suppose to be electric lamps. If the exhibition was lighted by electricity at night, the general effect must have been very pretty. The display of honey was not only very carefully arranged, but it was a very large one. Our friend D. A. Jones, of the *Canadian Bee Journal*, estimates that the exhibition building where the view was taken is about 27 ft. wide, 96 ft. long, 12 feet at the sides, and 27 ft. at the gables, with a self-supporting roof. The friends across the water, as well as the Canadian commissioners (who took no small part in this display) are to be congratulated for their enterprise in thus taking advan-

A VIEW INSIDE THE COLONIAL EXHIBITION.

From the picture our readers will readily gather that the English have a fondness for making large and elegant displays of honey, both comb and extracted, in various sizes and kinds of packages; not only that, but they take great pains to make each package look as attractive as possible. You observe in the long row of exhibits shown in the foreground, that some of the counters are arranged in pyramids, and others in terraces. The arrangement is certainly very artistic, and the effect must have been pleasing.

If our memory serves us correctly, Mr. Abbott informed us, when here, that there was not only one row of exhibits like the one shown, but there were six others of equal size and beauty. As if the display of honey were not fine enough in itself, our English brethren have summoned the aid of floral

tage of this very potent means of advertising. We learn that this honey-exhibition was of such general interest that the English papers gave quite flattering notices of it—notice which were calculated to tickle the palate of the English people at large for good pure wholesome honey. We also learn that the Canadian exhibit of the Canadian commissioners attracted no small amount of attention, both as regards the quality of the honey and the style of package. "Amateur Expert," in the *C. B. J.*, gives it as his opinion that the commissioners must have realized \$5000 from honey sold. So much for advertising in this way. Would that we Americans, with all our push and inventive genius, might bestir ourselves to something more extensive in the way of honey-exhibits! The only real honey-displays that we get up here are those made at our county fairs,

which, in comparison with those displays of the English, are very meager indeed; and even the exhibits at our State fairs are rather small in comparison with what they ought to be, as a rule. Our friend J. H. Martin, however, whose exhibit we showed on p. 89, is rather an exception. But the English people are vastly in advance of us in the art of getting up a first-class honey-display; and even our Canadian neighbors across the line are leaving us rather behind. If there were more of this disposition to show our honey before the masses, and thus utilize one of the best means of advertising, we firmly believe there would then be less cause of complaint over the low price of honey, and less uncharitableness toward the middlemen, and, at the same time, the press of the country would receive a more intimate knowledge of the manner and method now practiced for producing honey. They would see that it is possible to produce honey by the ton honestly. It would not only do much toward advertising our products, but do much to counteract the false statements in regard to our favorite pursuit.

ERNEST.

OUR CELLARS.

FRIEND TERRY ON THE VENTILATION OF.

FRIEND ROOT:—When going around the country in winter, attending farmers' institutes, I am often taken down cellar to see the potatoes, you know. Quite possibly I have noticed some things that the owners did not. Not always, but in the majority of cases, perhaps, the cellars under our homes are not properly kept, according to the best light we now have. This is my excuse for what follows:

You know very little of the health-giving sunlight, which I have urged the lady readers of *GLEANINGS* to let into their homes, gets into the ordinary cellar; in fact, we do not want it there, if we store vegetables therein. Potatoes in particular should be kept in the dark. Very often the cellar is damp as well as dark, and it is rarely ventilated. Perhaps it is banked up in the fall, and left closed, so far as doors and windows are concerned, all winter. Now, we know that sunshine and dryness and ventilation are necessary to make the air in our houses healthful. The air in the cellars having almost none of these, it must be more or less unhealthful. Then, again, probably in the majority of cases, there are some rotten vegetables to be found therein, or an old pork-barrel with stinking brine in it. Perhaps the ceiling is covered with cobwebs between the joists (I wonder if the ladies know how much cobwebs have to do with hastening decomposition sometimes). In such a cellar you will see mold on the wall, and the air is full of germs, or spores. Let in a ray of sunlight through a small hole in a curtain, and you can see these plainly with the naked eye. Hold a candle under this streak of floating germs, or particles, and instantly they are all destroyed above the blaze, whether they are vegetable or animal, and you make a dark spot in the streak of light, as there is nothing there to stop the light, and hence enable us to see it. Now, all will agree with me that the air in such a cellar is not such as we ought to breathe. But some one says, "We do not live

down cellar; what is the difference? We can stand such air for a few moments while we are necessarily down there." Well, let us see. What is there between your cellar and the rooms above where you do live? Just a matched-board floor and a carpet, perhaps, and the stoves have dried the boards so the joints are quite open. This is the way it usually is. Now, in the winter you have fires in your houses, and these fires take considerable air out of the rooms, particularly if you have grates. More air must be sucked in. Some will come in around the doors and windows; some will be drawn up through the floor. The tighter the doors and windows, the more will come from the cellar. Come it must from some quarter. Then won't you have to breathe it? Do you doubt that the impurities in the air will come through an inch board? At the institute in Marietta, Dr. Carl Leo Mees, of the Ohio University, passed coal gas through a brick. It was brought to one side in a pipe, and collected in a pipe on the other side, and lighted, the brick being covered with a gas-tight substance. Dr. M. told us that air would go through just as easily, and that all injurious germs would go with it, as he could show us. Now, I think all will say that the air would go through a half-open floor more easily than through a brick, and take its impurities with it. At any rate, our best scientific authorities now tell us that this is the case.

Again, some persons may say, "We have breathed these germs for years, and no harm has come of it; what is the use of worrying?" As Dr. Mees said, these germs may not of themselves be injurious; but suppose they have found lodgment in your lungs, partially filling up the air-passages, and then pneumonia comes along, and you need every bit of air-space you have got. These "harmless" germs may then cause your death. Or suppose some tramp or peddler brings into your home on his clothes a single germ of an injurious kind that can feed on the germs already in your body. It gets deposited there, and finds a splendid feeding-ground all prepared, and multiplies with lightning-like rapidity, and perhaps within a week an entire family dies, or the larger part of them. We often hear of just such cases. You may say this is theory; but do not facts go to prove it? When disease breaks out, such as diphtheria and scarlet fever, think where they rage worst. As long as scientists teach only what accords with common sense, we had better give heed to their doctrines, even if we do not fully understand or fall in with the germ theory. They do not fully understand it themselves; but they are making rapid strides in that direction. Well, now, practically, what shall we do? In a word, keep the air in your cellars *just as pure as you can*. Because the cellar is out of sight, do not let it be neglected. Keep it just as clean as any room in the house. There is no other safe way. First of all, make it *dry*. In selecting a place for a house, always choose a dry piece of land. If the house is already built, do not spare drain-tiles and labor until you have made the cellar as dry as possible. Next, plaster it overhead, without fail. Air will not go through mortar nearly as easily as through a brick. Then put building paper under your carpets instead of straw. Be sure to whitewash your cellars all over once in a year or two. Have a cement floor, and keep it clean. If you have reason to suspect there is any thing wrong (it will do no harm any way), fumigate

it by burning rags first dipped in melted brimstone. When it will do no harm, let in the sunshine. Most of all, do not allow any decaying vegetable or animal matter to stay in it. Now, then, my masculine friends, do not make your wives see to this. They have enough to do; but tend to it yourselves, as you value the lives of your dear ones. One may live over a damp filthy cellar for years, and not pay the penalty; but he can not tell how soon a day of reckoning may come. He may bury every child within a week. If science teaches any thing whatever plainly, it is that pure air, sunshine, and pure water, are the best preventives of disease. Make the air of your homes (cellars and all) as pure as possible. Under this head you want to look out for the slop-drains, or about emptying the slops always in one place. The safest way to manage sewer-gas is not to have any. This is the way at our home, as told of last year. About drinking-water, in my next letter.

T. B. TERRY.

Hudson, O., March, 1887.

Friend T., I am with you exactly in every word you say. Our cellar, where the steam-pipes are, contains nothing whatever. We got it up so high and dry, and put in so many windows, that it is too light and warm to keep anything, so we just partitioned off another part for our vegetables, etc., and this part can be aired and dried and sunned just as much as any other room in the house. By having it warm, we always have the floors of the room warm. We thought once we had got our cellar too high and too dry, and so it is for a potato-cellar. But I believe, especially after reading your remarks, that we can afford to have a potato-cellar somewhere else.

Now in regard to looking after our cellars, in a sanitary point of view: I have just returned from a visit to Prof. Cook's. While we were walking across the fields I was speaking of the wonderful progress we are making, and I asked him what he supposed the outcome was going to be of our wells of natural gas. He said that it would probably be beyond the conception of any one living, and then remarked that the next great stride to be made in science would probably concern human health and disease; and in answer to a question of mine, he said that it seemed to him quite likely we should soon have complete control of fevers, and diseases of kindred character. Now, then, it occurs to me, since reading your article, that perhaps we are beginning the march by taking up first the cellars that are under our houses.

OUR P. BENSON LETTER.

FEEDING OF BEES.

SUM people thinks bees ken feed thairselves, but that izzent sighthentfiek. Thay is diferent waze. 1 way is to feed them with a tea spoon. A table spoon is too big; thay let it run out of the side of their mouth. Throw your left arm around the bee's neck, while you hold the tea spoon in the right, and hug him pirty tite till he begins to gasp for breth, & then kwick pore the spoonful of feed down his throte. This

way is not to be reekommended, for the reeson the bee is ap to strangel & coff, & waist the feed.

P. BENSON SHOWS HOW TER FEED A BEE.

Next the simplissity feeder. Lookin at it with a inexperienced i this seems like a good feeder. But it izzent. You see the troublle is thair is no place in partickler for the bees to go in & out. Suppose the bees start in for the feed, and a ro stands all round the feed soze no more ken git in. Them that cums next will stand waitin for a chants to git in, and when the first wuns gits filled thay will turn round and find the way all blocked up by the 2d wuns. So eech 1 will wate out of polightness for the uther to git out of the way, & neather ken git by the uther & so thale jist stand thare and wate & the thing woont wirk.

That's the buty of sigents. Now a common man wood hefto taik a simplissity feeder and giv it to the bees to see if it wood wirk. But a grate Sighentist like me ken think it oll out in a phue ows & see that it kant wirk, and then he doant need to try it.

Then thare's the shuck feeder & uthers witch mite be good, oonly the bees hefto wirk in the dark, and thay kant do that. Hwo ever herd of a bee gethering hunny from clovur in the dark? Thay doant wirk that way.

The only proper way to feed bees is with P. Benson's (thats me) patent, reversible, trantsparent, youreeky bee-feeder. This consists as herein set 4th substanshelly as folloughs, viz, to-wit:

A feed chaimber (see A in the pickter) or its equivalent, in combinashen with a apertoor B, or a apertoor B in combinashen with a feed chaimber A, substanshelly, or its equivalent and for the purpusses set 4th, the whole to be constructed of vitreous glass or its equivalent, and the apertoor B, so constructed that exit and entrance to the feed chaimber A, may be effectoolly surceased through the apertoor B, by means of the thum of the operater, preferably that of the right or left hand, plaist upon the apertoor B.

P. BENSON'S
PATENT RE-
VERSABLE
TRANSPARENT
YOUREEKY
BEE-FEEDER.

To operate the feeder, the apertoor is left open a suffisient lenth of time for a suffisient number of bees to enter the feed chaimber A, then the operator poots his thum on the apex of the mouth of the apertoor till the bees are seen to have filled thairselves and arraing themselves in a boddly at the apertoor to git out. The thum bein removed thay rush 4th in sitch a boddly as to carry all before them, when a noo force enters as before.

P. BENSON, A. B. S.

MRS. HARRISON ON DISPOSING OF OUR HONEY-CROP.

ESTABLISHING HONEY-ROUTES, ON THE PLAN OF MILK-ROUTES, ETC.

THERE is no subject before the house that comes nearer to us all than the best way and means of disposing of our honey. If a bee-keeper loads up his honey and ships it to a large city, and sits down to smoke he will, in many instances, have time for a pretty long smoke before he has any returns for his season's labor.

There are few localities where there are not more than one hundred colonies kept, which would not be able to consume all the product. I once stopped at a farmhouse, five miles from any town, where forty colonies were run for extracted honey. The proprietor said, "I never take away a pound of honey; the neighbors come with their jars and pails, and take it away, and I could sell much more if I had it. I can not half supply the demand."

Farmers formerly, in Illinois, consumed large quantities of molasses. They bought it by the barrel or in kegs. Emigrants from Pennsylvania missed their fruit-butters, for which they are so famous, and the large family of "spreads" scoured through the woods in search of wild plums, grapes, and berries, and finally succumbed to the inevitable, and ate molasses. Since the advent of glucose-factories, molasses and syrups have gone by the board. Fruit is more abundant than in the early settlement of the country, but it does not entirely fill the gap. This class of consumers are almost entirely neglected by producers. They think honey is something to be sold to town-folks. How one of our Western farmers would laugh if you should ask him to buy a pound of honey! "A pound of honey? Why, that wouldn't be a lap. Bring me fifty or one hundred pounds." He has no use for a ten-cent package.

Those who farm here have large families; if not many children, they have work-hands, comers and goers, and there are few days when strangers do not sit down to their tables—agents, peddlers, etc. What a bonanza would honey be to the over-worked wife! It needs no cooking; she doesn't have to stand for hours, either, over a hot stove or by a fire out of doors, with smoke or ashes in her eyes, moving a stirrer back and forth all day, and at night till the clock strikes the little hours, to finish it off as it boils and sputters. This class needs instructing in the use of honey, and they could be easily taught, if it were only brought to their notice.

We never shipped any honey more than once, and that was owing to the severe illness of Mr. Harrison; and if we had employed the young man who packed and shipped it to have peddled it out, we should have saved money and worry, as he had been in the peddling business. During the winter, in most localities, there are plenty of young men out of employment, well fitted, with a little instruction, to sell honey. It would be better to trust them with our property than to ship it to entire strangers.

I'm not ashamed of the business, but proud of it—glad that I'm a producer of a pure sweet. In peddling honey, the better way when it is sold from house to house would be to go forth as the apostles did, by twos. One could drive the team, and abide by the stuff, while the other could exhibit the honey and solicit orders. The best assistant would be

one who has been over the ground before. A honey-route, in time, would have a commercial value the same as milk-routes now have. A family that uses honey at all buys a good deal, while there are others who can not be induced to use it; and in going over the ground the second time these could be left out.

Large producers must, of course, seek distant markets; but "it is the little foxes that spoil the vines." Small producers must sell their own honey at home, if they would succeed. Make honey legal tender for every thing they buy.

Peoria, Ill.

MRS. L. HARRISON.

You make a good point, Mrs. H., where you say that honey needs no cooking. Many times I have brought company home unexpectedly, and I would hear my wife say, "Well, there is *one* thing they can have right away, and that is some nice honey. Probably they are not used to it, and it will be a treat to them, and it can be produced in a twinkling," and it always turns out as predicted—it is praised and relished. And, by the way, you remind me of the time when mother and I used to make apple-butter away along into the night. Sometimes the wind was contrary, and blew the smoke into our eyes, etc. Your idea of having a honey-route, something on the plan of a milk-route, is certainly a good one. As honey is not perishable, of course the trip need be made only at intervals of a week or even more; but I am sure a regular system of this kind would pay well.

THE KITCHEN AGAIN, AND THE BEES.

MRS. AXTELL DISCUSSES WHETHER WOMEN ARE CAPABLE OF MANAGING AN APIARY.

OUR kitchen, I think, is the most cheery room in the house. A bay window is in the south; and on the north door, where the screen-door fits in in summer, is a tight-fitting wooden door, thus making a double door. There are two window-sash for the window, making the window double. This makes our kitchen very warm, light, and sunshiny—almost like summer in zero weather when the sun shines, and my four canaries seem to think it is summer, as they fill the house with their sweet music, seeming to sing because they can't help it. One would be surprised at the warmth the sun gives, as it reaches half way across the kitchen. In the upper half of our south door is a glass window, so that almost the whole south side of our kitchen is glass. In summer time the windows are all raised except the one in the door; and by the use of our gasoline stove the kitchen is about as cool as outdoors.

Our apiary is located just south of our kitchen, so that, when the bees swarm, we can readily see each colony and be on hand—a great convenience to a bee-keeper.

The sides and ceiling of our kitchen are finished in wainscoting, the whole painted a reddish pink, which does not grow dull or dusky by age, as blue or brown colors do if smoked a little. If finished in hard wood it is very easily washed. In cold weather, when boiling clothes, and the room is moist from steam, a soft cloth pinned around a broom, and the

steam wiped off the ceiling and sides of the room occasionally, keeps the room clean and healthful.

I do not think it healthful to live above a cellar, unless the greatest care is given to remove all decaying vegetables, and moldy boards and barrels, and dead bees from the bee-room. One winter we went west for a visit, and were gone one month. We left the house unused, except as our hand came into watch the temperature in the bee-cellar, and to open the cellar door when too warm. When we came home the rooms were dripping with moisture from the bees (about 125 colonies in the cellar). Even on the door of the clothes-room, water stood on the inside in great drops, and the bee-room is plastered overhead. There seems to be a great deal of moisture exhaled from the bees, so that it is well to have a stove in a cellar to keep the bees dry as well as warm; if damp and then cold, I think it gives them watery honey, a cold, and the result is the dysentery.

Our bee-cellar is 20x20 feet. In it we have at date 113 colonies, packed above and at sides of brood-nest with straw. We find, at a temperature of about 42°, our bees keep the most quiet, so that we have had to build a fire in the bee-room a good many days this winter. A few times the room became heated to 60°, but no harm ensued. By opening the ventilator (sub-earth) and cellar door it soon cooled off sufficiently, and the cellar walls seemed dried off. The air being purified, the bees were still and quiet. Bees need pure air as well as human beings do. If the cellar smells impure, the bees become uneasy, even if the temperature is all right.

The past season has been one of prosperity to us. Honey has been low, but every thing else has been correspondingly low. I do not think we should be discouraged at all. Each one should develop his home market, and trade as much of his honey as he can for things he has to buy. We have never had a season yet but that we could have sold much more honey than we had. We ship the greater part of our honey to Chicago.

Last winter we lost but four colonies in wintering, and those were nuclei. We united late, and did not know that queens were accepted.

We began the spring of 1886 with 130 colonies. Our increase, by natural swarming and building up nuclei, was 77, and we took 12,000 lbs. of comb honey. We keep our bees in two apiaries. Mr. Axtell takes care of the one from home, as I have often mentioned, while my hired girl and I take care of the one at home, and do our housework. I don't see but that we are just as successful as he is, and he as we are.

HANDLING FRAMES INSTEAD OF HIVES.

We manage our bees without lifting the hives very much, as neither of us is very strong, and hives are heavy; but we carry frames instead of hives, or, if necessary, take hives to pieces and carry in parts, as they are not nailed, but clamped at corners with a movable bottom-board. If it becomes necessary for me to work alone, I have a small express wagon, as it is called. I can work a rack out backside of hive, and place upon the wagon, and pull it into the honey-house; or if in a honey-harvest, I can pull the rack of honey out back of hive and let it stand upon a nail-keg until noon or night, and have the hand carry it in. I have not for years dared to carry a pail of water, and yet I can do all necessary work with bees without over-lifting; yet it pays me better to have a helper with

me to do what lifting is to be done, and to take steps for me.

I often get stung, but I do not fear bees any more than I would sitting hens—not half so much as I do our cattle and horses.

If a person is able to do any work at all, I can not see why bee-work is too hard, as bee-work is easier for me than housework. I look forward with pleasure to the coming spring, that I may again live with my bees. No months are so delightful as May and June, when I entirely release myself from all other work as much as possible, and live with bees, birds, and flowers. Before the summer is ended my health so much improves I can do as much or more bee-work than my husband, though, perhaps, I can not go through as many hives as Ernest can.

Roseville, Ill.

MRS. L. C. AXTELL.

Perhaps I should explain to our readers, that Mrs. Axtell uses a closed-end Quinby frame, therefore she can take the entire brood-nest, or a part of the brood-nest, out of the hive, leaving the bottom and sides undisturbed. We are very glad indeed to hear of the good report you made again last year, and we are also very glad of the suggestions you make in regard to having air and sunshine in our kitchens. As you are suffering from poor health, you are probably, like myself, more sensitive to the lack of air and sunshine than most people; but the very minute I am writing these words I feel that I must get out into the open fields, and into the bright sunshine. I have been all over the factory, looking after things that needed my attention and suggestions, until my brain is tired; in fact, I feel just now as if there were but little left of me, any way; but I know by experience that half an hour outdoors, where nobody shall ask me any questions, and where I shall not be importuned to read something, and *read it understandingly*, will make me feel like a good strong man again. It seems to build me up, as it were. I have been so many years reading these letters, and deciding on the contents, that I have lately got into the habit of reading a letter clear through, and not knowing a word of what I have read. My reasoning faculties refuse to "catch on" unless they are obliged to by mental effort, and I find it is as necessary to get outdoors among the chickens, or down in the lots by the brook, and dig in the dirt, as it is to take my accustomed food and sleep. God made the open fields and outdoor air and the sunshine; but I have sometimes seriously questioned whether he ever intended that man should make kitchens and offices where human beings were to be shut up, say more than half of the hours of daylight. At this time of year we have about 12 hours or more of daylight. Now, if I could take every other hour outdoors I could accomplish a good deal. I presume likely I should enjoy it to be outdoors during *every* hour of the twelve, but that can not very well be. This we can do, however: We can have lots of windows without any curtains to them, and we can have them swing open so easily, or rise up by weights, that even invalids like you and myself (?) will not dread the effort required to swing them wide open when the weather will permit.

The trouble with me is, that few people can bear the amount of air and sunshine that I crave and revel in; but I think it would be better for them if they could bear a little more. My wife visited a sick-room recently. She said, when she got home, that, if she could have her way, she would have a stove and fuel equal to the task of keeping the room warm for the patient, with one or more windows open all the while; and in talking with the doctor about it afterward, he said he honestly believed such a course would do more good than medicine—that is, as a matter of course, getting the patient *gradually* accustomed to so much air and sunshine. When I am obliged to stay indoors when I do not want to, I have found an open window to be the next best thing. Of course, I want to be clothed accordingly, and I want to sit facing the window, which should be open on a side of the room where there is not too strong a breeze. None need fear that they are going to be harmed by this sort of medicine—that is, it is a sort of medicine that leaves no poisonous drugs hanging about the system.

SENDING TO MR. ROOT FOR GOODS.

SOME HINTS ON BUYING IN GENERAL.

EVER since Mr. Root commenced selling the sort of goods in which he now deals, I have traded with him; and having some experience in that line I think it may be a useful thing to give the friends some of the benefit of my experience. I find that many things on his list are so much lower than usual prices that I can well afford to pay a pretty heavy rate of freight. But it does not pay to send for a very small quantity in some cases—perhaps in most cases—unless it be something so light that the postage will be little. For instance, I am partial to Dixon's axle-grease for wagon or buggy, and can not get it here. It is on the 10-cent counter; but a 1-lb. box sent by mail would cost 28 cts. postage, and that would make the box cost me 38 cts., at which price I would rather use some other kind. If sent by freight, a single box would cost me still more; for in sending freight the railroads charge so much per hundred, perhaps \$1.00 per hundred from Medina to Marengo (may be less than that, but that figure will do for illustration), but a minimum price is fixed upon as the least charge for a box or package, no matter how light it may be, and this minimum price, I think, is usually the price for 100 lbs. Mr. Root will correct me if I am wrong. So, if I send for a single box of axle-grease by freight it will cost me \$1.10—worse than by mail. If, however, I sent for 100 lbs. or more of goods, the freight would cost me only about one cent per pound; so by sending for quite a number of articles at a time I can save money by getting them from Medina. I think many others at a distance might save in the same way, so I will tell how we manage.

About once a year, or oftener, we take Mr. Root's price list, look it over carefully, and check such articles as we want to send for, perhaps letting some of our friends know of it, and letting them send with us. The difference in price of a single article may sometimes pay the freight. For instance, I bought a force-pump and paid \$2.00 for it in Ma-

rengo, feeling quite satisfied with my bargain; but in a short time Mr. Root advertised precisely the same thing for \$1.00. By thus looking over the list, and checking off those things that we need, or will need, within the year, we can make out quite a list; and the danger may be, in some cases, that Mr. Root's price list is so attractive, and so many things look cheap, that things not needed will be sent for, with the thought, "It's only 5 cts. or 10 cts.," but enough of these low-priced articles will amount to a considerable sum, and it is a good plan to buy nothing that is not really needed. Now, I will tell you about some of the things on the list, only a few, for of course we have not had all. Mr. Root has, of course, told about them, but it may be a good plan to know what others, who have tried them, think. First, there's wire nails. I don't buy of him now, because I can buy at home, and freight is heavy; but if you can't buy at your own stores you ought to send for at least a few of each kind, from ½ inch to 2½ inches, and you will, I think, never want to be without them again. Of other bee-keepers' supplies I will not speak, as you know probably what you need in that line.

Now take the list of the counter store, and glance over it. On the 3-cent counter, among the glass-ware, you will find some 2-cent articles made of wood. Never mind the incongruity. They are basswood nest-eggs, and I think look more like the genuine article than any glass or porcelain ones I ever saw. Then on the same counter are pins at 3 cts. a paper. Cheap, but I wouldn't buy them if I were you. They're iron; and wherever you use one, if it gets the least damp, through perspiration or otherwise, it will rust and spoil the clothing. But on the 5-cent counter you will find some excellent ones at the rate of about 60 for a cent, and you will probably pay a good deal more for them at your store. You can also get a pyramidal cushion of pins on the 10-cent counter, but they are no better pins, and no more of them, than in the 5-cent papers, and the cushion is not convenient to use over again, as it is simply a paper of pins rolled up and finished off quite prettily.

You can get some fine bargains in tinware from Mr. Root, if you understand what you want. Let me tell you something about buying tinware. The other day we got a box of goods from Mr. Root, and among them a 6 and 8 qt. pail. They are of light tin, and, used for water-pails, would last only a short time, or for any purpose where they are kept wet or washed very often. For such use it would be economy to pay twice as much for a pail made of good heavy tin. But I didn't get them for that purpose. It is real handy to have plenty of covered pails in which to keep cake, cookies, fried cakes, etc., and these light, cheap pails answer just as well as any for this purpose, or for any thing where they are generally kept dry. For milk-pans or any tinware wet or washed much, I find the higher-priced articles the cheapest in the end, and the re-tinned goods are especially desirable. Of these, Mr. Root has some away down below what I can buy them for at the hardware store, and they are beauties.

On the 5-cent counter are coal-shovels; and it's so handy to have one in each place where they are likely to be used, that I have four of them in different places. If I kept only one, and had to run for it each time I wanted it, the time thus spent would be worth a good many shovels.

If your wife has always used a wooden potato-masher, just get her a wire one off the 5 or 10 cent counter, and see how pleased she will be to have something so light and nice, making quicker and better work. I don't know of any way in which a small sum of money can be spent to give greater satisfaction than by getting a lot of these household conveniences for the benefit of the women-folks; and it's wonderful what patience they display in working along year after year with a scarcity of utensils that would never be endured by men-folks. There's the matter of pot-covers. I've seen them struggle along month after month, making a plate or a pie-tin do duty as a pot-cover, and do the duty very poorly at that, when all the time Mr. Root's price list hung in plain sight on the kitchen wall (a string should always be put in to hang them up by, Mr. Root), anxious to suggest that excellent tin pot-covers of six different sizes could be had for 5 cts. each. Then a woman will have a hard time scraping out her pots and kettle with a knife, when she could do it so much better and easier with a 10-cent dish-cloth of iron rings. There's many a farmer who does not hesitate at all to pay 25 or 50 dollars for some tool for farmwork, who could get along without it and hardly feel the difference, and for half the money get articles from Mr. Root's list that would save his wife hours and hours of time and toil, and make her life ever so much pleasanter. And it's often from sheer ignorance that he doesn't do it—ignorance on the part of both man and wife. Amongst the things she should have is a *good* carpet-sweeper. I got two, and they were successively thrown aside; but the one I got from Mr. Root is regularly used, and esteemed a great help. She should have a good supply of real *sharp* knives for various uses, and they should be kept sharp. Get her a \$3 or \$3.50 grindstone, such as Mr. Root used to keep, and she can do her own sharpening. I don't know why he doesn't keep them now, unless because they are a little difficult to straighten up when they get out of kilter. Possibly the grindstone on the 75-cent counter will answer, but I haven't tried it. She needs a good bread-knife with a rather wide blade. Mr. Root has a good one for 10 cents, if it would only stay in the handle. Then on the 10-cent counter is a butcher-knife she needs. I got one with a blade about $4\frac{1}{2}$ inches long; but the last time he sent me one with a blade 6 inches long. They are both good, but the short one is the favorite, perhaps for old acquaintance' sake.

Looking further down on the 10-cent list is "knife, kitchen, fine steel, with beautifully finished handle." I got one of these, and it fully answered the description, and was so well liked that my wife gave it to a friend and told me to get another. The other came in the last box, but was entirely different. The handle is *not* beautifully finished, and the knife is a most outlandish-looking thing. But, oh how nicely it works! While writing this I stopped and laid down before my wife the eight different kinds of sharp knives we happen to have, and asked her which she valued most. She said it wasn't fair to ask such a question, but she could tell me which two she would rather have. "Well, then," said I, "which two?" Without saying a word, and without a moment's hesitation, she picked up this uncouth-looking thing, and then went to studying which she would take for a longer-bladed knife; so that, after all,

the ill-favored kitchen-knife, I think, is the most treasured, and I wouldn't take 50 cts. for it if I couldn't get another. For paring potatoes and other things, I never saw its equal. If you ever sat and pared apples or other fruit for a long time, you know how black your index finger becomes where it rests on the back of the knife-blade; and, if continued long enough, the finger becomes sore. Well, some genius has gotten up this knife with the handle projecting about three-fourths of an inch more on the back of the blade than it does on the edge, so that the fore-finger rests on the handle instead of the blade. If you don't expect to send for a box of things soon, better send Mr. Root 14 cents and have him send you one of these knives by mail, right away.

For a pocket-knife, my favorite is the Barlow, on the 15-cent counter. I think I have had more than a dozen of these. They are handy to give away, and will take an edge almost like a razor; and if your boy loses one, the loss is not very great.

Instead of having the children buy a leadpencil every little while at the store for 3 or 5 cts., you had better get a dozen from the 10-cent counter, making them cost less than one cent each.

While I am writing this I am wearing a pair of spectacles from the 10-cent counter; and, between you and me, I believe they are just as good as if I had paid \$1.00, \$2.00, or \$10.00 for them. I don't know, but I *think* there is a great deal of nonsense about this matter of spectacles, Scotch pebbles, and all that sort of thing. If the glass is perfectly transparent, and of homogeneous texture, what more can there be, except the shape? I believe there are many people whose eyes are really injured by wearing high-priced glasses, because a pair of glasses that was bought five years ago does not fit the eyes now, but they cost so much that they are endured, to the injury of the eyes, rather than pay so much for a new pair. I haven't any that cost over 25 cts., so I can keep one pair always at my writing-desk, and one in each of my vest-pockets, thus running no risk of being caught every now and then a mile from home with no glasses.

Until Mr. Root gets some better suspenders, don't buy any from him.

The cheapest way to buy needles, and have them good, is to get a package from the 15-cent counter.

If you want an egg-beater, don't get the cheaper ones, but get a Dover, from the 25-cent counter.

Of course, I have mentioned only a few articles, and some unmentioned may have more merit than some I have mentioned; but I thought it would be useful to the readers to say what I have.

Marengo, Ill.

C. C. MILLER.

In regard to freight, friend M., to get the best rates on it the shipments should not weigh less than 200 lbs. Many of our railroad companies have a special lower rate for 200 lbs. or over, although 100 lbs. will go pretty nearly as cheap as 200. The way the basswood nest-eggs got into the glassware, some one thoughtlessly put them with glass nest-eggs, in order to have *nest-eggs* all in one place.—The iron pins at 3 cts. a paper are like the cheap tinware—just as good as any for certain purposes. For instance, we use them here in the office for pinning papers and letters together. You see, our clerks are pretty much all women-folks, and

they take to pins a good deal as ducks do to water. Perhaps it would not be well to have these iron pins taken into a family where they might be used in such a way as to do damage.

We have *also* the best quality of tinware; but as our covered pails are mainly used for honey, to be given away with the honey, they are our great specialty; and by the way, friend M., it makes a great difference who uses the tinware. A few days ago I asked my wife how long a certain utensil had been in use; and although it is a piece of tinware, she said she had used it almost ever since we were first married. I told her I would throw it away and get a new one, simply for looks' sake, if for nothing else. Her invariable habit, however, is to have tinware cleaned and wiped dry, and put up on the shelf every time it is used. We never leave water standing in any tin utensil, unless it is the water-pail, and I believe that is always upside down (taking a rest, as it were) in the night time. Rubbing occasionally a little of some kind of grease that contains no salt, in the joints, or on places most apt to rust, will also aid greatly in making tinware last. Some people, however, say this is too much trouble, and that they would rather have a new one once in a while, and so they get a new wash-basin every summer—a new dipper perhaps oftener, or new water-pails, in the same way.

I am glad that you found out what that uncouth-looking handle was intended for, friend M. In the appendix to the Potato-Book Mr. Terry mentions that their women-folks always get their fingers sore in cutting up potatoes for seed, and directs that you wind a rag around the fore-finger, etc. Now, this knife has the exceedingly thin fine steel blade he advises, and the handle projects up along the blade so as to form an easy natural rest for that same fore-finger. I think we shall have to have a picture of this knife, as it seems to be so exceedingly handy for so many purposes.

In regard to spectacles, I presume you know, friend M., that for a good many years of my life I stood behind the counter and sold spectacles. A good deal of the time my father stood with me, and we examined faithfully and carefully the so-called "pebble-glasses," and compared them with manufactured lenses made of a fine quality of clear flint glass. Both of us soon became satisfied, and the testimony of dozens of customers still further satisfied us, that almost as good glasses could be furnished for a few cents as could be bought of the so-called opticians for a good many dollars; and I have for years advised my friends to use such spectacles as we sell at 25 cts. If they want something that will answer out in the fields, to lay down on the work-bench, or so as to have a pair in each pocket, get three or four pair of the ten-cent ones at the same time. One of the ladies who attends our teachers' meetings owns perhaps half a dozen pair of spectacles. Some of them cost as high as \$2.50 or even \$3.00, but she declares positively that a pair she got of us for ten cents are a good deal better glasses than the highest-priced ones. I presume the

truth is, that some of the ten-cent ones often suit the eyes exactly, by what we might perhaps call accident. The very glasses we sell for 25 cts. are often sold for \$2.00 or more. The jewelers and opticians who do it, justify themselves by saying they can not get along and pay their rent and other expenses unless they have great profits on certain lines of goods. It looks to me, however, as if they might as well say they could not get through this world comfortably by doing as they would be done by.

Friend M., we have not been able to find a manufacturer of suspenders yet who would give us such goods as we want. If there is a manufacturer of this line of goods among the readers of GLEANINGS, we shall be very happy to make his acquaintance.

BUMBLE-BEES.

A FEW MORE FACTS ABOUT THEIR HABITS.

WHEN at home on the farm, a lad of some 15 years, I was made interested in honey-bees by some neighbors cutting down a tree, robbing them of their stores, and leaving the bees, which I secured, yet of no use more than to awaken a more lively interest in bees and their habits, as it was fall, and the queen was killed. The next year father bought me a colony of bees in a movable-comb hive, and from that time on I have ever been a lover of bees. About this time I took a notion to try and get a colony of bumble-bees, so I made a box about six inches square, with bottom board projecting, and a $\frac{3}{4}$ -in. hole for entrance; for a cover, just a piece of board held on by a stone. I do not remember just how I got the first nest into the box, but I did, and every nest that I could rob I added the brood part to it, and let them hatch. They made quite a strong colony. By the way, there are two or three varieties here. One kind is small, with about half of the abdomen a shiny black; another kind with a band of red hairs across the abdomen. This is the kind we boys liked to rob; it is true, they are more vicious; but with that there was more honey. I fancy there is also a large yellow kind, not so good for honey-gathering. My colony consisted of these three varieties working harmoniously together. About July or August I lifted up the lid. The cells were just shining full of honey. Thinks I to myself, there will be a fine treat after awhile. Well, one morning, when I thought the flowers were failing, I lifted the lid again and "peeked in;" and just at that time a bee "peeked out" and flew perpendicularly to the side of my eye. While smarting with pain I was much inclined to give the box a kick and send it across the garden; but I did not, and need not tell you why. Some days afterward, noticing there was not much stir about the hive, I lifted the lid again, and, to my horror, nearly all the bees were gone and all the honey consumed.

I have seen the drones and queens mating quite a few times; also toward fall, on a fine day, I have seen one or two dozen drones flying about where a nest is situated, and young queens, among them. I have also robbed nests when there would be several young queens besides the old one. I have found them in spring with one cell of honey and one containing pollen and an egg in it, together

with just the queen. You can easily distinguish the drones from workers; for while workers are a shiny black at the rear of their abdomen, the drones keep the same color to the end, and are a little more blunt. We used, when boys, to call them "she bees." They may be found on what we call "bull thistles" and other fall flowers, earning their own living by the sweat of their brow.

THOS. STOKES.

SOME USES FOR HONEY.

FLAVORS TO USE WITH HONEY, ETC.

I WONDER if any of the readers of GLEANINGS have had any thing like the following experience of ours happen to them. Several years ago we sold several barrels of fall honey to a large grocer and dealer in sweets, in a city in the east. One of the barrels was to be used in a bakery. A few days after the honey had reached its destination we received a letter from the wholesale dealer, saying: "I do not know what to do with the barrel of honey which I delivered to the baker; he says he spoiled a batch of cakes by using it. I have tasted the cakes; they have an unpleasant flavor."

We knew that the quality of the honey was unquestionably good, so when my husband read that letter to me we looked at each other in surprise. The honey that we used for the cookies, "snaps," and honey-cakes that were daily on our table was of the very same quality as that which was in the aforesaid barrel; and not only did we prefer the strong-flavored honey to spring honey for baking purposes, but many who had tasted these cookies, etc., at our home had seemed to relish them.

After thinking the matter over a few minutes I realized what the trouble was: The baker had probably tried to make *gingerbread* with this fall honey. I had once tried to use ginger to flavor cakes and cookies made with fall honey, and the result had been a decided failure—the two flavors combined giving a coarse, bitter, almost nauseous taste. I have used ginger with honeys of milder flavor; and though the result is not perfection, the taste is not really bad.

A number of different flavors can be used with honey; among them are cinnamon, nutmeg, grated orange-peel, etc. But by far the best flavor is obtained by the use of the four spices—*anise-seed*, *coriander-seed*, *cinnamon*, and *nutmeg*. So far as I have experimented, I have found the following to be the best recipe for

HONEY SPICE-BREAD.

Dissolve a teaspoonful of soda into $1\frac{1}{2}$ cups of sweet milk at least 3 hours before you are ready to mix the cake (soaking the soda the day before is still more preferable). Have ready 3 cupfuls of honey, 4 eggs, $\frac{1}{2}$ cupful of butter, and one tablespoonful each of ground *anise-seed* and *coriander-seed*, one scant teaspoonful of ground *cinnamon*, and $\frac{1}{2}$ *nutmeg*, grated. Melt the honey, if candied, but use it cold, or only lukewarm; mix it with the butter and the spices thoroughly; add flour enough to make a stiff batter; next add the yolks of the eggs and the milk, mix and beat well, then add the whites beaten stiff. Bake in square tins in a gentle oven. If the dough lays in the pans over an inch and a half in thickness, allow it to bake 45 minutes to one hour. One-half hour is enough if

the cakes are not thick. When poured in the pans the batter should be of such consistency as to spread evenly in the pans though not too readily.

SOFT HONEY-COOKIES.

Mix together 3 cupfuls of liquid honey, 5 eggs, a scant cupful of lard or butter, and a heaping teaspoon of soda; add the four spices mentioned above, and mix with enough flour to make a stiff dough; roll out *thick*, cut in any shape, and bake in a quick oven to a light brown.

CRISP "HONEY-SNAPS."

To two cupfuls of honey add one or two eggs, half a cup of butter, half a teaspoonful of soda, spices as in the above mixtures; make a dough just stiff enough to roll (if you let it stand in a cold place after mixing it soft, it will get stiffer without using more flour). Roll it out thin, cut in any shape, and bake in a slow oven until quite brown.

The soft cookies will get too soft unless kept in a dry place, but the "snaps" will remain crisp quite a while, and keep fresh for a long time.

Cinnamon, *anise-seed*, and a small proportion of cloves, may be used as a substitute for the four spices mentioned above, though they are by no means a perfect substitute. In the above recipes the strongest-flavored honey will give the best results.

Any cake or cookies made with honey is far more digestible than compounds of sugar, eggs, and flour. Ginger, as every one knows, is a tonic of a very irritating nature, while *anise-seed* (or the essence obtained from *anise*) is one of the few flavors which can be used by dyspeptics with actual benefit. Every mother who has used Mrs. Winslow's soothing syrup knows it owes its soothing qualities chiefly to the essence of *anise-seed*.

Coriander grows wherever carrots grow, so we bee-keepers can not only produce our own sweets, but that with which to flavor them.

I intended to say much more about honey and its uses, but my article is already too long. I may come again, and show the advantages of using honey in making jams, and give two or three more recipes.

MRS. E. J. BAXTER.

Nauvoo, Ill., March, 1887.

A REMEDY FOR THE MUCH-DREADED GREEN FLY OF THE LETTUCE-GROWERS.

A KIND OF FOUL BROOD THAT BRINGS RELIEF INSTEAD OF DISASTER.

MR. ROOT:—I am just home after a week's absence, and find the green aphides of the lettuce, which you send, all dried up. Yet I assure you they are very interesting to me, for I can still see the fungoid threads which would surely soon bind them in death's chains if they had not already done so. While we are very loth to have the fungus of "foul brood" carry off our bees, we are more than willing to have it claim as victims our injurious insects. As I told you at Ypsilanti, the cabbage-caterpillar fungus is destroying the destructive pest of our cabbages in a way to make every cabbage-grower glad. That fungus is much like the one that kills our bees; while the one you send that is ensnaring the aphids is like that which is often seen enshrouding our common house-flies in autumn. Nearly all the readers of GLEANINGS

have doubtless observed the white mold, or fungus, on house-flies in autumn, and have seen the flies succumb to its embrace. A close examination of the carcass of the fly shows that the mycelium, or threads, of the fungus, have passed all through the victim's body. These aphides which you sent seem to be attacked by a similar fungoid parasite. It is a very interesting fact, and may be possessed of no small practical importance. If a few of these hairy lice could be carried in a letter, say to some other greenhouse, and there set free, very likely they would fasten their deadly grasp upon other of these aphides, and thus one of the worst pests of the greenhouse would be stamped out. Entomologists have done many valuable services by importing parasitic insects, and scattering them, that they might perform their goodly mission in other and often widely distant districts, and have thus fought insects which could be overcome in no other way. It looks as if we might have another equally potent weapon in these vegetable parasites. These fungi on plant-lice are new to me, and I would take it as a favor if you would send me some fresh ones, when I will see what I can do by way of cultivating them here.

It now looks as if these fungoid organisms, the source of death in plants and animals alike, were soon to be thoroughly understood through the researches of scientists. Then we shall be able to escape harm from disease which they engender, and also to make them our servants in slaying our enemies.

A. J. COOK.

Agricultural College, Mich., Feb. 21, 1887.

In answer to the above, I would say that we have, during the last part of the winter, been watching curiously the green flies in one of the upper beds in our greenhouse. When half grown or fully grown, their bright green changed to a reddish pink, and finally the insect gave place to a spot on the leaf, something like a minute drop of reddish paint. The disease has now extended to the green flies in other parts of the greenhouse; and the prospect is, that it will increase so as to destroy the whole of them, without the aid of tobacco-stems, small chickens, or any thing of that sort. If other lettuce-growers have noticed a similar phenomenon, we should be glad to hear from them.

HANDLING BEES IN EARLY SPRING.

H. R. BOARDMAN ON THE QUESTION OF WINTERING.

I HAVE just been reading *Our Own Apiary* in last issue of *GLEANINGS* (Mar. 1), and I was a little astonished that you did not take out the frames and make a careful examination to ascertain the exact condition of some of your colonies. To be sure, winter is a poor time to be tinkering with bees; but we have had quite a number of warm days when bees could be handled in the sun without any possible danger of doing them the least bit of harm; and we are all a little interested in knowing the condition of the bees at the Home of the Honey-Bees, at the very earliest opportunity. I am very certain that you would have found brood in nearly every colony some time ago if you had looked. I am quite particular in these matters, and will not be satisfied with guessing; and of those wintered inside I set out a few colonies

on occasional warm days for examination, that I may know just what is being done.

I am wintering 30 colonies on their summer stands, scattered about at four different apiaries, for the purpose more especially of perfecting some experiments in downward ventilation in outdoor wintering. Here at the home apiary I have eight of these colonies. On turning to my journal I find this entry:

Jan. 29.—Warm and pleasant. Bees outside flew nearly all day. I have examined four of the eight colonies on summer stands here at the home apiary, and found sealed brood in all of them, with more or less larvæ and eggs surrounding it. The extent of brood-rearing is astonishing for the time of year. The patches of sealed brood are four to six inches in extent. I set but two colonies from the bee-house for examination, and found no signs of brood or eggs. And again:

Feb. 10.—Temperature 56°. I opened one of the hives examined on Jan. 29th, and found a large amount of brood, still more than there was when examined before about two weeks ago, the frames being nearly full, with eggs and larvæ surrounding the sealed brood, and also in the center, where the brood is beginning to hatch. And again:

Mar. 1.—Temperature 45°. I examined a colony on summer stand, and found an abundance of brood with eggs and larvæ, and some old pollen in the combs. This colony has already bred up quite strong, and has more bees now than at the commencement of winter. I had expected to find some damage done the brood by the severe cold of the last few days past, but did not even see any brood thrown out by the bees.

I might say that these colonies were of average strength; had a fair exposure to all of the trying weather of the past winter, with no protection whatever, with only a $\frac{1}{4}$ -inch board between them and outdoors. They have been in good condition at all times during the winter. Now, I would suggest that we jot this item down on the tablet of our memories.

Bees wintered on their summer stands do sometimes begin brood-rearing earlier than those wintered in cellars or bee-repositories.

The downward ventilation may have had something to do with the early breeding, but I attribute it more to the warm spells of weather.

My bees "inside" are wintering in fine condition, and have, at this date, commenced breeding quite extensively.

H. R. BOARDMAN.

East Townsend, Huron Co., O., Mar. 4, 1887.

Friend B., I am well aware that bees many times do well when handled in the middle of winter; and I am inclined to think that, if handled only when they can fly, little if any injury would be done. I have several times, however, known bees started to flying by this kind of handling, where others that were not handled did not fly at all—or none of any consequence. I have also known the weather to turn around suddenly in the winter, and even before the disturbed colony had got settled. Under such circumstances a great many bees would be lost, and the colony seriously injured. An old experienced hand might safely go through his bees in January, if he thought fit to do so. I believe that handling in winter, as a general thing, seems to start brood-rearing. I have

rarely found brood chilled by being handled in cold weather, unless the frames were carelessly put in different places, so that the cluster would be unable to cover the brood that had by this means been pushed out of the cluster. We did make a thorough examination March 10th, and found brood in perhaps one-third of the whole number of colonies; and, by the way, I believe I would rather that bees should not commence brood-rearing very much, before the middle of March or toward the first of April. This matter has been much discussed, I presume you remember, in our back volumes.

DRONE COMB.

FOUNDATION, EMPTY FRAMES, ETC.

I THINK Mr. Dadant is entirely correct in his views about the building of drone comb; i. e., if the brood-nest is so large that the bees in the first-built cells hatch before the brood-nest is filled with comb, and the queen returns to the center to refill the cells with eggs, then the comb that is built will, quite likely, be drone comb, *because the bees are building it for storing surplus*. You will see that I have no trouble from this source, because I contract the brood-nest to such an extent that it is filled before the bees in the first-built cells hatch, hence the queen is always close upon the heels of the comb-builders. If the honey-flow should suddenly cease before the brood-nest is filled with comb, and comb-building should be stopped as the result, until bees were hatching in the central combs, and the comb-building should be resumed at exactly this time, it is quite likely that drone comb would be the result.

You say, friend Root, that you are loth to give up the axiom that "empty combs are the sheet-anchor of bee-keeping." I do not ask you to give it up; only not to use them in the brood-nest when *hiving swarms*. This question of when, where, and how, to use empty combs; when fdn. is preferable to combs; and when it is better to allow the bees to build comb than to use either, is one I have tried to make as clear as possible in the little book that I have written the past winter. The book is now in press, and will soon be out.

Friend Root, I am just a little puzzled by your remarks on page 174, about 8 and 10 frame hives. Heretofore you have approved of 10-frame hives; and your remarks on page 174 are, *apparently*, in their defense; yet you close by saying, that so far as the amount of bees is concerned you don't see that there is much difference. If we can raise as many bees in an eight-frame hive as in a larger one, why not give it the preference, and thus save the expense of the extra combs? W. Z. HUTCHINSON.

Rogersville, Genesee Co., Mich., March 9, 1887.

I will try to make my meaning clear, friend H. Early in the season, before the colony has increased or enlarged sufficiently to have any use for more than 8 combs, the bees and brood in an eight-frame hive are worth just as much as the bees and brood from a ten-frame hive; in other words, for quite a spell in the spring of the year we find most colonies with two or more unoccupied combs that do the bees no good whatever, and I prefer the ten-comb hive, because, when the time comes that the 10 combs are

needed, there they are, right at hand. If they contain sealed stores, they are also right at hand for the bees when they want them. Were I purchasing bees and brood, however, as we do purchase almost every spring from our neighbor Rice and others, I would just as soon have the bees and brood from an eight-frame hive as from a ten-frame hive. In buying bees, we stipulate to get combs enough with them so as to take all the brood and pollen and no more, for we do not want to purchase any more extra combs than are absolutely necessary, preferring to have bees build them in wired frames, for our special use. I think that, when neighbor Rice brings us bees the first of May, it requires only from five to eight combs to contain all the brood and pollen in a good colony.

THE T SUPER—THE BEST ARRANGEMENT.

HONEY, HIGH AND LOW PRICE OF.

I AM glad to see in GLEANINGS, p. 156, that you are giving the public a good description of the T super, for it is by far the best arrangement yet made for holding sections. The first one I ever saw was made by my brother, and used in our apiary in Front Royal, Va., in the spring of 1883. Since that time we have made hundreds of them for the eight and ten frame L. hive, also for chaff hives. It works nicely with or without separators. But we always use them with, as we like to have our sections of uniform weight, and built so they can be crated without damage to combs. For the eight-frame L. hive we make the cases 12½ inches wide, inside measure, and run the tins the long way of the case, thereby putting in three rows of sections, the sections running crosswise of the brood-frames. We are convinced that the bees do not fasten bits of comb to them nearly as much as when they run the same way as the brood-frames. By using the T-tin bearings for sections they are brought down to a bee-space from the frames, and the cases are more easily cleaned of propolis than any other we have tried. We use a follower at the back end of the case, to hold the sections and separators snug, either with a wedge or thumb-screws. As we use nothing but 4¼x4¼ sections, we have the T tins fastened at fixed distances in the case, so that they are always in the right place. The case can be made so as to have a bee-space over the sections or not, as desired. We use them without, and slide the cases on from the side of the hive when tiering up.

HONEY A STAPLE ARTICLE OF FOOD.

I shall have to side with Mr. Dadant as regards the prospect of honey competing with sugar and syrup. I am convinced that, when honey is placed in the hands of the consumer, at a fair price as compared with the wholesale prices now obtained for it, there will be large quantities of it used, where now it is hardly known. While stopping in New York and Philadelphia on my trip to my old home here in New Hampshire, I saw tons of comb honey in the hands of commission men, that could be purchased all the way from 9 to 12 cts. per pound. The same honey in the retailers' hands was being offered at 20 cts. A large part of this honey was dark, and of light weight, so the consumer had to pay

25 cts. for what he ought to have for 15 cts. This, I believe, is the principal reason why more people "do not like honey." I have never yet seen the person who preferred cane syrup, or the other manufactured syrups, to nice honey, when it could be had at a fair price; and, in fact, nine out of ten persons in our community tell me they care but little for any other sweet.

The only way I see for the bee-keepers to increase the sale and consumption of honey, and at a price which will pay them for their labor and capital involved, is to place the honey in the consumers' hands, in good shape (which can not be done after it has been through the hands of two or more middlemen), and at a price which a laboring man can pay. When this is done, honey will not be a drug on the market, as it is now becoming. We must all work hard to create a local demand instead of holding conventions to keep prices up.

Oxford, N. H., Feb. 28, 1887.

H. W. BASS.

DRONE COMB, AGAIN.

DOOLITTLE CONSIDERS DADANT'S THEORY.

IT was with great interest that I read Chas. Dadant's article on drone comb, in *GLEANINGS* for Feb. 15; and I wish to say that I consider that what he calls his "theory" is mainly a fact. The only thing I can not fully indorse is the idea that the queen has control of the matter of comb-building. This I doubt; but as the facts regarding the building of both drone and worker comb remain exactly the same as Bro. D. gives them, I do not know that it makes any particular difference which it is, bees or queen, that controls the matter. As bearing directly on this subject I wish to give a few more points not touched upon by friend D., or only partially explained by him.

In preparing for swarming, the old queen begins to cease her prolificness some three days before the swarm issues, so that, during the last 24 hours, only a few hundred eggs are laid, as nature has provided that the queen should not be cumbered with eggs to such an extent that she can not fly when the time for swarming comes. There is also another reason for her doing so, which bears more directly on the comb question, which is, that, when the swarm finds a natural home, there is no comb in it, hence no place for eggs, even if the queen could lay the 3500 eggs D. speaks of her laying the first 24 hours. As a rule, it takes 8 hours after a swarm is put in an empty hive before there is a cell formed deep enough to have an egg placed in it, while with an ordinary swarm, comb-building does not become extensive during the first 24 hours. By this time the queen is ready for her part of the work, after which we find it is just as friend D. states. Now, any thing which keeps the queen from following the bees right up with eggs as fast as the comb is built, tends toward drone comb; hence the putting of one empty comb in the brood-chamber, as I saw recommended by a writer in one of our bee-papers lately, is just the thing to fill the hive to a large extent with drone comb, as years of former experience proved to me when I thoroughly went over all of the ground. It would take the queen so long to fill this comb with eggs that the bees would get the start of her; and no worse advice could be put in print than this writer gave.

Again, the giving of a frame of brood to prevent

decamping is subject to the same objection, providing there are empty cells in it, or nearly mature bees, which will hatch to any extent so as to cause the queen to leave off following the bees. Again, a very large swarm, as where two or more swarms are hived together, is sure to build quite a share of their comb of the drone or store size, for the reason that they build comb faster than the queen can occupy it with eggs. Now for the reason why the plan as recommended by Bro. Hutchinson has a tendency toward the building of only worker comb in the brood-chamber: There is little room for comb below, and lots of room above, while the room above is made enticing for the bees to build comb there first, as in the surplus-apartment a start has already been made, so as the most of the comb is built there for the first 24 hours. They now begin below; and as the queen is now ready for business she keeps up with the comb-building here while that which would tend to exceed her prolificness is built in the sections. Now, if for any reason the bees fail to enter the sections and thereby all crowd into the small hive below, thus building comb very fast here, so as to get the start of the queen, the small size of the brood-chamber or the presence of surplus room on top has no effect whatever; and I here state as my belief, that something of the kind has been the trouble when success has not been attained. In other words, having too full sections, so that not enough room for the surplus of bees was given; too much room, so the bees were loth to enter the surplus-arrangement; or an unprolific queen, has been the cause of the failure, for I have used it successfully for 14 years, and was the first to describe it in connection with securing all worker comb.

One other item: After 21 days have elapsed from the time of hiving a swarm, if any more room is added to the brood-chamber it must be given in the shape of empty comb or comb foundation, for drone comb is sure to result, as the instinct of the queen takes her back over the former ground, rather than to lay in newly built cells. From the above the reader will see how my fourteen years of experience agrees with friend Dadant's article. However, I find, contrary to what I read, that nearly all of my prime swarms having a queen a year or more old will rear a few drones within six weeks from the time of hiving, so I consider the idea fallacious, that new swarms do not build drone comb for the purpose of rearing drones. With me there are always a few square inches built for this purpose, no matter how well suited to the building of worker comb my plans are. Then, too, my earlier swarms often swarm again, in which case they will have drones, even if they have to tear down worker comb so they can build drone. Hoping the above may throw some light on what the editor calls "deep water," is my excuse for this article.

Borodino, N. Y., March, 1887. G. M. DOOLITTLE.

Friend D., you have no doubt thrown some light on this matter that I have called "deep water," and I see now how it is that the position that you have held so long and tenaciously is going to agree pretty well with friend Hutchinson's new developments. The new developments slip over on to ground we have already traveled, although many of us did not see it until you pointed it out, only you did not recommend, or, at least, I do not remember that you recom-

mended, placing sections ready furnished, right over the brood-frames, where the bees were to build their own comb. You did, however, strongly insist that the bees could be made to build their own combs, and have them all nice straight worker combs at the same time.

CIDER, AND ITS EFFECT ON BEES.

HOW TO TAKE DOWN A SWARM 30 FEET FROM THE GROUND.

IN this locality cider is always made after the frosts have destroyed fall flowers. If the bees fly at this time they are sure to get more or less of it. If they get just enough to keep the queen laying, and yet no more than will be used up in brood-rearing, then it may be a benefit. You know we Canucks are great on young bees for winter. During the fall of 1884, also in the fall of '85, my bees gathered just enough to produce that effect. A very cold winter followed the fall of each year, accompanied by no serious results to the bees. But this fall the weather was fine during cider time, and they gathered a good deal more than they used before winter. After a confinement of 90 days they had a flight—Jan. 22d and 23d—hardly warm enough for a good flight, but each colony flew some, and all showed more or less signs of dysentery; some were badly affected. There is very little honey-dew in this locality; and that the cider was the cause of the diarrhea I have not the slightest doubt. In fact, I do not think we need doubt any more about it. Any cider left in the combs after winter has set in is a very undesirable addition to their stores; and to make a clean sweep, keep the cider away from them altogether if possible.

CONVENIENCES FOR THE APIARY.

The solar wax-extractor I have found a great help in getting nice wax. There is nothing I have ever tried that pleases me better. It is certainly less bother, and a great improvement on the Swiss extractor. Mine is so nearly like one described in GLEANINGS last summer that I shall not attempt a description.

TAKING DOWN SWARMS THAT CLUSTER HIGH.

For this purpose I have found the Shepherd hiving-box too cumbersome and heavy. The hoop-and-bag arrangement described in the A B C is not open to this objection, but it is liable to get torn when placed among the limbs. Allow me to describe a contrivance of my own, a trial of which I think will please the readers of GLEANINGS. Take a common stout cane fish-pole; saw off the end about 10 feet from the large end, and four or five inches from one of the joints. Now fit a piece of hard wood in the small hollow end; have it long enough to reach the joint, and saw it off even with the end of the pole. About two inches from the top, bore a small hole through the side of the pole into the plug. Now get a common wire hook, screw it into the hole, clear through the pole. Next hunt up those fruit-baskets that you bought fruit in last fall, and have no other use for (if you don't happen to have them, you can buy them for seven cents each); select a good strong one. You will notice that it is just about the right size and shape you want—about 14 inches across the circular top, 7 inches across the bottom, and 12 inches high. The spaces between the splints will be about $\frac{3}{4}$ inch. If you think that too much, you can stick a half-inch

splint between the interstices, and fasten with a half-inch wire nail. Now tie a stout cord across the top of the basket; take your pole in one hand, and with the hook pick up your basket. Can you imagine any thing lighter or nicer? In fact, the whole affair is strong enough and yet very light. If the cane is not obtainable, ash or hickory makes a good substitute, but not quite so light. You may need another pole with a hook on it to shake the limb with. If your apiary is large, one pole will answer for a number of baskets; and with a little practice you can pick them up on the run. If another swarm comes out while you are shaking one in a basket, just snap a cloth cover over the top; set them in the shade, and then hive them at your leisure.

Now let me tell you how this arrangement saved me a fine colony of bees last summer. A large swarm clustered on a tall maple near my apiary. They were about thirty feet from the ground, and at the extreme end of a limb about 15 feet from the body of the tree. I had just about given them up when I thought, "Here is a good chance to see what I can do with my pole and basket." After placing a ladder against the tree I saw that I still had considerable climbing to do; but "my blood was up," and I was bound to have that swarm. I soon found that I could reach the swarm, but was obliged to hold my hiving-basket and pole nearly at arms' length, almost horizontal, which I could not have done, especially when the swarm dropped, had the pole or basket been heavier. Well, I got the bees in all right, pulled in the pole, detached it from the basket, caught hold of the cord with one hand (the limbs were in easy stepping distance), and I soon reached the ladder. Now, thought I, I will hook the basket on and let it down to Mrs. D., who stood at the bottom of the ladder. I had just started to lower it when off it slipped from the hook and down came the basket, right side up, however. The bees sat down in the bottom, but we got them in the hive. Had it not been for my light hiving-basket, I should have been obliged to make the return of the Southern sheriff—*Non come atibus in swampo.*

Ridgway, Ont., Can.

J. F. DUNN.

BEE-STING POISONING.

A SIMPLE REMEDY IN SEVERE CASES.

IN GLEANINGS of Feb. 15, 1887, Mr. Ellison, of South Carolina, after speaking of the serious effects of bee-sting poison upon two members of his family, says: "It would be a great boon if some of our bee-keeping fraternity who belong to the medical profession would study a remedy for cases of this kind, and give it to us."

While I do not belong to the medical profession, I think I can give him a remedy for the constitutional effects of bee-poison—a remedy that can have no bad effect, that is always at hand in every home, that is prompt in its effects, and one that I believe will not fail to cure if quickly applied. I will give a case in point.

On a hot day in summer, some fifteen years ago, my eldest son, then about two years old, was stung by a bee on the back of his head. By the time he was taken into the house, probably two minutes, his face was considerably swollen. He grew rapidly worse, so that in a few minutes he was much swollen; his face was a livid or purplish hue, his

utterance became difficult, and he seemed to be losing consciousness. My first thought was to go to town, three miles away, for the doctor; but my wife said that it would be of no use, for what was done for our child would have to be done before a doctor could be called. At about this point I remember that I had read in the old *A. B. J.* that a "wet-sheet pack" was a cure for bee-poisoning. Our child was soon stripped of his clothing and quickly wrapped in a cloth from which the water had been wrung, just enough to prevent dripping. Outside the wet sheet he was snugly wrapped in dry blankets. He had been in the pack but a few minutes before the natural color began to return to his face, and the swelling to disappear, and in fifteen or twenty minutes the symptoms of poisoning had all, or nearly all, disappeared, and he was taken out cured.

Several years ago Mrs. Hayhurst, of Kansas City, gave in *GLEANINGS* an account of a similar case and cure that occurred in her family. Our daughter, when small, suffered from a severe scarlet rash after being stung, like that described by Mr. Ellison. It was quickly relieved by an application of the wet-sheet pack. I think she was thus treated for this rash three or four times. Both of these children gradually outgrew their susceptibility to bee-poison, and now make little account of bee-stings.

Dr. Trall, in his "Hydropathic Encyclopedia," recommends the wet-sheet pack in the treatment of poisoning from snake-bites, as well as from bee-stings, and I see no reason why it should not be as efficacious in the former as in the latter case. This treatment for snake-poisoning has some advantages over whisky, in that it is safer and more immediately available in the houses of most bee-keepers.

For the benefit of those who may not be acquainted with hydropathic appliances, perhaps I ought to tell how to put a person into a pack. Two or three quilts or blankets are first spread on a bed. Upon these a wet sheet is spread—as wet as may be without dripping. The patient lies on his back on the middle of the bed, with his head projecting above the sheet, and his arms raised. The attendant quickly draws one side of the sheet over the patient, drawing it tight and tucking it under, so that the sheet fits snugly. The arms are then dropped by his side, and the other half of the sheet is thrown over and drawn tightly and tucked under, care being taken to get a good fit about the neck and shoulders. The same process of covering and tucking up is repeated with the blankets until the patient has sufficient covering to keep him warm. Much sweating is not desirable, and twenty or thirty minutes is as long as one should remain in the pack. T. P. ANDREWS.

Farina, Ill., Feb. 22, 1887.

Friend Andrews, I can heartily indorse such remedies as you mention for bee-stings. Cold water will go very well with pure air and sunshine as a remedial agent. Another thing, it is not guesswork. Whenever any part of the body is inflamed and feverish, relief comes by cooling the inflamed part with wet cloths, and I do not know that any bad results ever follow. I have, however, many times tried immersing my hand in a pail of water after I had been stung, to see if it would allay the pain, and I have in-

variably noticed that it had no effect whatever. If, however, my hand should be swollen or feverish, from the effects of a sting, or several stings, then the bucket of water gives relief, and I am satisfied it assists without question, to bring about a speedy recovery. Indeed, where a patient is in danger of dying from suffocation on account of bee-stings, a wet pack might be the means of saving a life.

ALSIKE CLOVER.

HOW TO GROW IT WITH SUCCESS.

ANY land that will produce red clover will answer for alsike, or Swedish clover; and any one can grow alsike with success by simply mixing it with red clover and timothy, or orchard grass. The chief object in mixing the alsike with red clover is for the shade furnished by the latter in dry seasons. The main use of timothy, or orchard grass, is to hold the alsike up or away from the ground. The mixing of alsike with red clover is the secret of success in dry seasons, and on dry soils. In wet seasons, and on moist soils where the common red clover does not do well, the alsike will make a fine growth by itself; but even then it is better to mix it with timothy or red clover, or both. Some prefer orchard grass to timothy, as they claim it makes earlier hay and pasture, and of better quality. Orchard grass makes a rapid growth after cutting, and is as good as timothy for holding the alsike up. I hope those who intend to seed with alsike this spring will try some orchard grass in place of timothy, and report the result.

It is not generally known, that alsike can be grown with the best of success on land already seeded down to red clover or timothy, or both. By scattering the alsike early in the spring over pastures and meadows, the seed will catch and do well. Rye and wheat lands are perhaps the best to seed down, but I have had a good "catch" with oats and barley. July, August, and September are good months for seeding pastures and meadows with alsike. The summer and autumn rains will give the alsike sufficient growth to stand the winter and the freezings and thawings of the following spring.

When grown by itself, 4 lbs. of alsike is plenty for an acre; and when mixed with red clover or timothy, or both, 2 lbs. will be about right. The seed is as small as that of white clover; and as each seed that grows makes a large stool, a small amount is ample for an acre. It is safe enough to say, that one bushel of alsike will seed down as many acres as three bushels of the common red. This being the case, a bushel of alsike would be as cheap and as economical at \$15.00 as the common red at \$5.00. But as choice alsike seed can now be had at about \$7.00 per bushel, the reader must see that it is far cheaper than any other clover-seed at the present time.

The best time to cut alsike for hay is when it is in full bloom—say the latter part of June or early in July; but if wanted for honey and seed, the latter part of July in the Northern States will be about right. When mixed with timothy, more or less of the latter will be ripe also; but this does no harm, as the two should be mixed any way for general

purposes. But by cutting the alsike a trifle early the timothy will not be ripe enough to do much harm; and what little seed there may be then can be separated from the clover by a strong blast of the fanning-mill. Alsike may be cut for hay early in June, and before it comes into blossom. Of course, the hay will not be so good as when in full bloom; but by this means another crop can be secured, and the later bloom will come at a time perhaps when there is a gap in the honey-flow.

All things considered, I look upon alsike as the best plant yet discovered for bee-keepers to advocate, it being worthy of general cultivation for hay, pasture, and honey. M. M. BALDRIDGE:
St. Charles, Ill., Mar. 7, 1887.

A FEW SUGGESTIONS FROM AN A B C SCHOLAR.

LIMA BEANVINES FOR SHADE; HIVES AS HENS'-NESTS.

EDITOR GLEANINGS:—It is needless to tell you that I am a beginner in apiculture—my veridancy will show that. Nor is it necessary to tell you I am but eighteen years old; but I will, and I hope the older members of the bee-keeping fraternity will not consider me presumptuous in offering a few suggestions, for age has not made me cautious, nor adversity wise. The suggestions are ventured with a view to help my brother A B C's, and, also, to find out, by your timely advice, as to whether I am on the right track or not.

I started in 1884 with one colony of hybrids in an American hive, and, after many of the trials incident to novices, have now but seven colonies, three of which are mine and the other four I procured from a neighbor, Dr. C.—, on these terms, first resolving (as per your advice in A B C book) to remain good friends, even if I have to sacrifice the bees, etc. The terms are: The four colonies—two in Simplicity and two in American hives—are mine until the doctor calls for them, which he can not do for at least two years. During this time, or as long as I keep the bees, I am to have all the increase and honey, with the exception of 50 per cent of the surplus honey, which he is to get, as it were, for the rent of the bees. He is not likely to ever want the four colonies back again, as his profession engages his entire attention. Are these terms, in your opinion, mutually beneficial, if the present proves to be a good honey year? I am satisfied with them.

RECORD OF APIARY.

I have kept an "Apiarian Record and Account" ever since my advent in the bee-business. In this blank-book I record every noteworthy event or transaction occurring in or pertaining to my apiary. I also keep a "poultry record"—in fact, a record of every thing I do, for my own benefit. By having every queer streak or strange phenomenon occurring among my bees in black and white thus, I am not compelled to trust to memory—which is often treacherous—in regard to these things in future.

QUICK AND SURE SHADE FOR HIVES.

My small apiary is called the "Model Apiary," and it has been, and in future shall be, my endeavor to make it a model one in every way possible. I am now shading my hives with grapevines, etc., as per directions under "Apiary," in the A B C. Now, while I am waiting for the small grapevines to

grow sufficiently to shade the hives, at each post of the trellis I am planting Lima beans. About one month from now I shall plant more beans, which can be bearing after the first are dead. It seems to me that these vines at each hive will not only give a good shade—which shade, by attention, will not prevent the grapevines from growing—but they should yield enough beans to give us a home supply, and also to feed our chickens with, in accordance with your suggestion (a good one, I think) in GLEANINGS Feb. 15, 1886, page 155. This suggestion is merely given for experiment; and would it not be a good idea for several of the A B C class to try a few beanvines for shade, and report? I shall.

WHAT I DO WITH OLD HIVES.

I make hens'-nests in odd out-of-the-way places, with old American hives, because I have no other use for such hives, and, by taking out the glass under the door and leaving the door open, they make excellent nests. My hens seem to prefer them to improved nests. Sometimes I utilize Simplicities not in use, for the same purpose.

DRONE-TRAPS.

I see young chickens are mentioned frequently in GLEANINGS as drone-catchers. Last year I disposed of all my surplus drones in this way. The young chicks (several months old) never, to my knowledge, caught a worker-bee. I taught them to catch drones by feeding them a few near the hives, and then driving them up to the entrance, where they picked up nearly every drone that tried to get in.

HOW TO CARRY SIMPLICITY HIVES BY HAND SOME DISTANCE.

When necessary to remove a colony, in Simplicity hive, by hand some distance, it is tiresome, and a wagon jolts the bees too much to suit me. I nail a handle five feet long to each side of a Simplicity bottom-board, thus making a platform on which two persons can carry a colony without jolting. Put a sheet on the platform, place your hive on the sheet, double the sheet over the top of the hive, and you have your bees tight. If the colony is heavy, shoulder-straps may be put to the handles.

A WINDBREAK ON THE WINDY SIDE.

I have to-day planted sixty raspberry-plants in two rows, at a distance of two feet in the row, and rows two feet apart, on the northern, or windy side, of my apiary plot. The raspberries can be trained on suitable frames, and, besides the honey they give, may serve as a windbreak. The vines may also be converted into a fence to turn stock. I shall plant several hundred more near my apiary this spring. I have also planted 50 Concord grapevines.

I, for one, should like to hear more from the bee-keepers of this State in the columns of GLEANINGS, and I presume I shall, now that we have an Alabama Bee-Keepers' Association, with Mr. S. G. Wood, of Birmingham, as president, and Mr. J. M. Jenkins, of Wetumpka, secretary and treasurer.

Ashville, Ala., Feb. 24, 1887. WM. H. CATHER.

Friend C., Lima beans have been suggested already, and I believe used considerably, for shading bee-hives. They do not, however, branch out like the grapevine, so as to give just the shape of foliage we want. A sort of trellis, spread out a little fan-shaped at the top, might, however, make them do nicely. If the ground is made rich, the beans would pay well aside from their office of shading hives; but the tramping around them might not be so good for them, and of

course they would have to be hoed by hand, for we could not cultivate them among the hives. With your small apiary, however, that part could be got along with easily.— We have heard about your bee-keepers' association before. I think you have got a good start.

MAKING HONEY VINEGAR.

CAN IT BE MADE TO COMPETE IN PRICE WITH GLUCOSE VINEGAR?

ABOUT September last I received a gift from friend C. F. Muth, of a large jar of his honey vinegar. It was very fine, and I put it on exhibition at the State Fair here, where many tasted it, and would have purchased if I had had a supply. Some years ago, when I was engaged in the manufacture and sale of glucose, I sold tons of it to the vinegar-manufacturers; and from intercourse with them, as also from the study of books treating on vinegar-making, I became pretty well posted in the practical working of a vinegar-factory. At that time it suggested itself to me to use honey; but a glance at the value of honey versus glucose soon showed the folly of that thought, for I could sell highly converted grape sugar at 2½ cts. per lb., delivered, and honey was away up far beyond that. I lately began to think there was something in honey for vinegar, if it kept on going down in value, so I decided to look it up; and friend France's statement, on page 64, GLEANINGS for Jan. 15, gave me a basis of value. He says it takes two lbs. of honey to make one gallon of vinegar.

I called upon one of my old vinegar-making friends, and asked him to buy some honey. After quoting him prices that friend France would not like to deliver at, he chuckled and rather laughed.

"Ab, Todd, things have rather changed since you sold me glucose," said he. He then explained to me what I already knew, that by using corn, and mashing it with hot water in a peculiarly scientific manner, he gets, for less money, the equivalent of the pound of glucose that he used to pay 2½ cts. for.

"Why," said he, "I can buy raw cane sugar at 4 to 5 cts. per lb., and even that is not as cheap as making from corn."

In a short time I found that the cost of the raw material required to produce one gallon of vinegar from corn was 3 cts.; and from cane sugar nearly 5 cts. Now, taking honey at 3 cts., and say that 2 lbs. are required to make one gallon, that is 6 cts. as against cane sugar 5 cts., and corn 3 cts. Taking the percentage of water, waxy matter, etc., in honey into account, which reduce its effective saccharine value to not more than 85 to 88 per cent, I came to the conclusion that, to sell honey to vinegar-manufacturers, it will have to be offered to them at 1½ cts. per lb. Now, who will be first to ship me a carload to dispose of to vinegar-makers? My friend tested Mr. Muth's honey vinegar, and said it stood "27, soda test."

"At what price can you supply me a quantity of vinegar of that strength?" I asked.

"Six cents per gallon," was the reply.

Thanking my friend, I declined to sell him any honey just that day, and decided to give your readers the benefit of getting down to actual facts.

Although 1½ cts. per lb. may be the value to a regular vinegar-manufacturer who would buy honey as a source of "saccharine," yet to those who econ-

omize as friend France does, every drain of the cappings or washing of the barrels should be utilized. It takes only a little reasoning to see that, if they turn them into vinegar with a minimum of labor and expense, and can sell all their product at only 25 cts. per gallon, they are in reality obtaining the very nice profit of 15 cts. on each 2 lbs. of honey it took to make the gallon of vinegar. In other words, they sell their refuse honey to themselves at 5 cts. per lb., and receive a gross profit of 7½ cts. thereon. I think you will join me in advising them to continue their manufacture of vinegar, and even to try to extend it.

The French bee-men have always been very careful to let nothing go to waste; and out of the washings of the combs taken by the old ways, wine and vinegar have been made for ages. Yes, even the very water in which combs are melted up are utilized for vinegar. Having turned to page 339 of Hamet's *Cours d'Apiculture*, I find a singular corroboration of friend France's statements. Here is the paragraph translated: "The strength of the vinegar is in proportion to the quantity of honey to the solution. One-half kilogramme (one pound) can give two litres (quarts) of strong vinegar."

Philadelphia, March, 1887.

ARTHUR TODD.

It seems to me, however, friend T., that the vinegar made from glucose would be hardly equal to that made from honey, in the same way that we get a poor quality of almost every thing else when glucose is substituted for sugar or honey. The vinegar manufactured directly from corn, I suppose is equivalent to, or is exactly what we buy for white-wine vinegar. There are two kinds of vinegar generally in the market—cider and white-wine vinegar. The latter is supposed to be made from wine, hence its name. But of late, I believe it is made from corn or corn whisky. Now, we sell both kinds of vinegar. The white-wine vinegar has the whitest and nicest look, especially for bottling pickles; but almost everybody clamors for pure cider vinegar, especially where it is wanted for table use—to eat on pork and beans, lettuce, and the like. Good cider vinegar is generally worth 10 or 12 cts. per gallon at wholesale, and perhaps twice as much at retail. Now, if honey vinegar should get a reputation and name, it would be preferred to the white-wine or glucose vinegar, no matter how low the latter might be offered. The article on page 212 of our last issue throws some light on the subject.

HONEY VINEGAR.

FRIEND BINGHAM GIVES US A FEW MORE ITEMS.

PAGE 64, Jan. 15, exhibits a plan of ascertaining the amount of honey per gallon of water, and gives an egg as the means. If desirable to use honey in making marketable vinegar, no one can fail to see that 2 lbs. of honey will put an embargo on the business at once. If so much is required to produce an article retailing at 25 cts. per gallon, merchants and others will be slow to introduce it to their customers, provided, of course, the manufacturer must get pay for his 2 lbs. per gallon, and trouble and other expense in its shipment.

That two years is required to make such a com-

pound into vinegar is also a weighty article against economic use. While ordinary vinegar, said to be cider, is sold at wholesale per barrel at about 10 cts. per gallon, it would be useless to attempt to sell vinegar to a merchant for the value of 2 lbs. of honey, and necessary expense per gallon added. Any merchant would at once say, "The vinegar you offer will be part mother, and other waste, so that we shall not only pay for your honey and trouble, but a loss of several gallons will fall upon us, while the cider vinegar we sell holds out in measure, and we have no trouble with the mother and other matter not salable, left in the bottom of the barrel."

It is not that I wish to discourage any one in the effort to make vinegar; on the contrary, I have shown at conventions all the honey vinegar I have ever seen on exhibit at those places, and freely told how to make it. I have also written for the bee-journals, describing the process minutely.

With the egg-test, the only way to use less than 2 lbs. of honey per gallon would be to reduce the saccharine strength by adding one gallon of clear water to every gallon of honey-water that would float a fresh egg. Eggs are a very uncertain measure of specific gravity.

I have steadily maintained, that one pound of good honey would make one gallon of the best vinegar that could be made. I have evaporated the best vinegar I ever made or saw, and know that it does not contain quite one pound of honey per gallon.

I make a little sweetened-water tester which I sell to my friends for 10 cts., which is a test for vinegar-making, and will last a lifetime, and is always reliable. It will readily be seen, that vinegar containing 1 lb. of honey could be profitably sold at 25 cts. per gallon; further, that it will make in an ordinary house-cellar, in an open tub, screened with burlaps, in less than one year's time. I have beautiful candied honey evaporated from such vinegar as I have made and used exclusively in my family for the past 12 years, so you can get your honey out of such vinegar in case you should want honey more than vinegar.

HOW TO MAKE BINGHAM'S VINEGAR-TEST.

Take clear yellow beeswax, $\frac{1}{2}$ ounce, and two ordinary shot, $\frac{1}{8}$ inch in diameter. Heat the wax so it will be soft, and put the two shot into the center of it. Now make a ball of it like a marble. Its upper surface will rise just to the surface of the vinegar, or sweetened water, if it contains one pound of honey per gallon—just the amount needed for fine vinegar.

T. F. BINGHAM.

Abronia, Mich.

BEEES IN YUCATAN.

MORE ABOUT THE STINGLESS BEES.

ONE of our subscribers, Mr. J. M. Beatty, Shaw's Landing, Pa., sends us the *Meadville Gazette*. From an article on Yucatan and its climate, people, and productions, written by a Dr. Roberts, we clip the following paragraph, giving us an insight as to how they keep bees down there on that peninsula south of the Gulf of Mexico. We presume that the race of bees are the same as have been previously described as being found in some parts of Mexico.

Here we had an opportunity of seeing the manner in which honey is produced—one of the great staples of Yucatan, as large quantities are consumed by the inhabitants. We notice at one end of the beautiful garden a picturesque shed covered with tile. On inquiry we were told it was a bee-house, and upon examination we found it contained a large number of bee-hives of very peculiar construction. Under the shed was placed a framework running the whole length of the building—wide at the base and running to a point near the roof, thus forming a sort of inclined plane fronting outward on either side of the shed, or bee-house. On the sides of this framework the hives were placed. They are made of logs of wood about twelve to fifteen inches in diameter, and from two to three feet long, the inside being cut out, leaving a thin shell of the log. Each end is sealed up with clay or cement, and in the center of this peculiar hive a hole is bored just large enough to admit a single bee. These hives are placed on the inclined plane, or framework, under the shed, commencing at the bottom and laying one on top of the other to the top, with the hole in the hive facing outward. When filled with hives the shed presents the appearance of a log-heap, sawed up, ready to be split into stovewood. The bees are different from ours. They are a trifle larger, a little lighter colored, and have no sting—in this particular they are a great improvement upon ours. When in the hive they place a sentinel at the hole, and no bee is allowed to pass in or out, except such as have the permission of their guard. The sentinel dodges back to let the other bees pass in or out, but almost instantaneously his head is seen in the hole after the passage of the other bee. We watched these little sentinels a long time with much interest, and thought that if human beings, intrusted with responsible positions and duties, were half as faithful as these little sentinels, we should have a much more virtuous and happy world.

FIRST-CLASS HONEY, AND THE MARKET.

IS THE FLAVOR OF THE HONEY, WHEN LEFT IN THE HIVES, IMPROVED?

I CAN not agree with friend Russell, on page 46, nor with any one else, that "there is but a small proportion of the honey produced at the present day that is strictly first class." His statement is based on the idea that capped honey must be left on the hives until late in the season, that it may attain its finest qualities. This I consider a mistake. I believe comb honey is *finished* when capped, and the sooner it is removed the better. Many of our friends who have left honey on the hives until late in the season have stated that they found it to be finer in every respect. It certainly does *appear* finer when cut or broken or tasted; but as far as we can consistently go is to concede that the quality *appears* to be better than the same honey removed in the early part of the season. Honey taken from the hives in the heat of the summer will, of course, be softer and thinner than the same quality of honey taken in cooler weather, and after it has a little age. I think our friends who advocate leaving it on the hives till the close of the season will find that their capped comb honey, removed from the hives as soon as capped, and placed in the honey-house, will, at the same time of the year, compare favorably, and I may say equally, so far as quality is concerned, with that left on the hives. It certainly is not subject to the liability of becoming soiled or stained, as when left on the hives.

I think, as to the sale of our production, much more depends upon the manner of preparing, packing for shipment, and a few other things, than whether or not the perfectly capped sections be left on the hives until late in the season. We well know, that

of two cases of honey which the producer knows to be exactly alike, so far as quality, fineness of flavor, etc., are concerned, from some cause, one will be cleaner and clearer white than the other—at least nineteen out of twenty customers will select the clear white, even at a better figure.

I think there are many more important things to consider in regard to the future honey market than leaving perfectly capped sections on the hives for any length of time, as to our success in general. I fully agree with friend Heddon, on page 54, in regard to a special convention, as "there is much else to look after."

C. W. KING.

Kalamazoo, Mich., Feb. 10, 1887.

Friend K., although there is a great deal in what you say, I feel quite certain that the quality of honey is much improved by being left a month or two in the hives. Basswood honey, for instance, is unpleasant to many people, when first gathered. This is the case, even if it is capped over. Let it stand in the hive, however, until fall, and it increases in density, becomes darker colored, and loses the rank green basswood taste, becoming mellow and rich. I would not, however, think of treating sections of honey in this way. People who want old ripe honey had better have it extracted, or, if you choose, have such honey built in regular brood-frames, and then cut it out in chunks to put on the table. When sufficiently ripened, even basswood honey will get so thick that an extractor will hardly throw it out, and this kind of honey is the sort that pleases me. In transferring colonies in the spring we often get hold of nice chunks of this old ripe rich honey. I do not know that anybody has intended to recommend this sort, however, to put on the market. You are right in thinking that people will take the white clean honey every time.

FOUL BROOD.

HOW TO DETECT IT IN ITS EARLY STAGES.

AS spring is at hand, and as I understand it is generally admitted to be hard to distinguish foul brood in its first stages from chilled brood caused either by carelessness or ignorance, the following way will enable even the novice to detect it at its start. At this time its spread, and often a general epidemic among the bees in a large territory, may be avoided. In March or April, according to locality (and about the time when bees are looked after for other purposes), is your opportunity. Good colonies will have large sheets of brood in the center, just hatching out. Now, if in such sheets any cells remain unhatched, with the well-known little hole in the center, they may be, almost to a certainty, put down as having foul brood, and you had better stop all exchanging of combs, and prepare for the worst. It is too late when you can smell it outside or at the entrance, and such cases can occur only when a colony has not been opened for a long time. It costs but little if any more time to keep a lookout for it, when your eye is once accustomed to it. In case the disease is introduced by the feeding of but a little affected honey, as is generally the case, and therefore is, as yet, local, it may often be got rid of by cutting out the affected cells. In cases like the above, where every doubtful cell is carefully cut

out, and no new ones are appearing in about ten days after, and there is still doubt, a good plan is to put the colony to the swarming-test, which is as follows: Keep the brood-nest contracted; feed, if not much honey is gathered, and thereby compel the bees to swarm. This they will do generally, providing it is in the swarming season. As foul-broody bees are not supposed to swarm, this would prove their health.

C. H. LUTTGENS.

Hammon, N. J., Feb. 17, 1887.

A CAVE FOR WINTERING.

QUEENS FROM THE SOUTH NOT INFERIOR TO NORTHERN-BRED QUEENS.

IHAVE a cyclone cave, 6 x 9, excavated in the side of a hill, or knoll, deep enough so that the top of the cave is level with the surface of the ground, and it is grassed over as any lawn should be. This cave is lined with large sheets of tin, 7 x 9, top, bottom, sides, and ends, then ceiling up with pine lumber. There is a small ventilator on top, 6 x 6 inches, and a trap-door. For 87 days the snow has covered the door and all, and sometimes the ventilator. Of course, the cave is very dry within. In this cave there are 40 colonies of bees, in Simplicity hives, piled four and five deep. Between each hive is spread one thickness of new coarse muslin. One end of each hive is also raised one inch from the other. Now, I should like to ask, will the bees in the cave live? If they do, will they be in good condition in the spring? If the bottom hive and the one next above it shut tight together, as some of these do, what will be the effect on those two hives? The temperature of the cave in winter, when no bees are there, varies from 34 to 40°.

THE DIFFERENCE BETWEEN THE ITALIANS AND THE BLACKS.

My bees are within one or one and a half miles of bee-pasture. What honey the blacks do store in sections is capped very nicely—nicer, I believe, than that stored by Italians; but my blacks do not make the amount of honey Italians do; so from my limited experience I have to say, that, surrounded by white clover or timber, blacks will store as much, perhaps, as Italians. But where honey must be carried any great distance, I believe the Italians far excel the blacks. I have had some experience with different strains of Italians; that is, in the last two seasons I have received by mail, from different States in the Union, over 50 Italian queens. I had an idea that queens from the Southern States would produce bees less able to withstand the cold of our Northern winters, and be less ambitious. I am now satisfied, however, that this is a mistake. Last summer I had some dealings with our friend I. R. Good; and from him I obtained 10 nuclei from his apiary in Middle Tennessee. Those bees would be the first out in the morning, and the last in at night, rain or shine. This may not prove any thing, perhaps; yet I am perfectly satisfied that Southern bees are not lacking in ambition when moved to the North. My first queen came from E. M. Hayhurst, Kansas City, Mo. At that time there were only three or four pure Italian queens in my vicinity. Wishing to have a few Italian bees of my own rearing, after the black drones were about all gone I bought one dollar's worth of Italian drones from A. I. Root.

They came by express. Through that strange experiment I was fortunate enough to raise three purely mated queens, the progeny of which suit me the best of any I ever saw.

J. W. PORTER.

Ponea, Neb., Feb. 8, 1887.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

ALSIKE.

THE alsike clover-seed I got from you last spring came up and grew splendidly, but the dry weather in July and August killed all that I sowed on old timothy meadow, being about 25 acres. But I sowed some in my orchard, and I could not ask for a finer stand. The ground had been planted in potatoes the year before, and the potatoes were thrown out in the fall with a plow. I dragged the ground crosswise until I got it well leveled down, then I spread on the seed and dragged it well after that. This I did March 27th. The weeds came on thick and fast; but as soon as they got up enough to begin to shade the clover I shaved the ground over as closely as I could with my mower. Then the clover grew very rapidly, and was soon showing bloom. I was surprised at this, as I thought it did not bloom until the second season. I want to sow more the coming spring, but shall sow it on well-prepared ground.

C. M. LEWELLING.

Western Nebraska, Feb. 7, 1887.

Your suggestion in regard to mowing off the weeds is a good one, friend L. I suppose one reason why alsike seldom blooms until the second season is because it is put on to oats, wheat, or some other crop of grain. If sown early in the spring, and given the entire ground, keeping the weeds out as you suggest, until the clover starves them out, it will, I believe, give a pretty good yield of honey the first fall.

SHIPPING SWARMS OF BEES ON ONE FRAME OF HONEY.

As I am a reader of GLEANINGS I should be glad to have you give your opinion as to the practicability of shipping full swarms of bees on one frame of honey, to provision them on their journey. As it would take no longer to make a light box to hold a swarm than to make a cage to hold one pound of bees, I am of the opinion that bees so shipped would save a great deal of time in putting them up, and could be sold at reduced prices if they can be shipped successfully by the swarm. I have more than I can manage well, and I should be glad to have you give your opinion, for my benefit as well as for others so interested. As to preventing swarms on Sunday, as spoken of by C. M. G., page 100, Feb. 1, I think the plan would work with black bees, but I think it doubtful whether it would work with Italians, as I have had them swarm with not a queen-cell started in the parent hive.

W. A. SANDERS.

Oak Bower, Hart Co., Ga., Feb. 21, 1887.

Friend S., generally speaking I do not know that there is any better way to ship swarms of bees than on a frame of honey—that is, so far as getting bees safely to their destination is concerned. This comb, how-

ever, must be old and tough, or it will get broken in transit; but as we find it difficult to get a sufficient number of such old and tough combs built securely fast to the frame clear around, we have adopted the plan of wiring combs. Then, again, when the purchaser receives the bees, this frame may not fit his hives. In that case it is of little or no use to him. For this reason we use our shipping-box in preference, for a half-pound, or one or two pounds of bees. When we sell a colony we always use frames of honey, or, better still, a frame containing both brood and honey.

SEPARATORS NECESSARY.

In my experience in the production of comb honey, I have come to the conclusion that separators are necessary, if we want honey that can be handled with any degree of satisfaction; but I believe we can work successfully with two for each case. Let us take a section-case for illustration. Divide it into three equal parts, with two separators. If the case holds 24 sections there will be eight in each division. Now, when the center one is all capped we take them out and put in empty ones, and every thing goes on all right; but if we don't put in a separator between the empty and the full boxes they will build the full sections into the empty ones; and when it is filled it will also be built into the adjoining one, and so all through the empty boxes put in the center, and that will be 8 boxes spoiled, and the row each side will also be bulged on one side; that makes 14 spoiled by taking out the center and replacing empty boxes without separators. Now, by using two separators we can get fair combs without tiering up.

North Springfield, Mo.

W. H. RITTER.

No doubt you can get along very well, friend R., in the manner you mention; but would it not be cheaper to use more separators, and not have so much manipulation, especially where 100 colonies or more are to be gone over?

DO NOISE AND JARRING INJURE BEES?

I have seen in GLEANINGS that noise prevents bees from doing well; and to the end that a proper conclusion may be arrived at, I beg to make the following report: I have ten colonies of bees in the yard of my residence. These hives are within ten feet of the house, and some of them directly under our windows. They are all about one hundred feet from the Central and the Western Railway of Alabama. Over these two roads there pass at least fifty trains a day, at all times of the day and night, and they sometimes jar the house in which we live, and so must jar the bees also. I thought for some time that the jarring, whistling, and ringing of bells, as these trains pass, would injure the bees; but so far (and the bees have been there a full season or nearly a year) I can discover no injury to the bees from the trains. They wintered exceedingly well, and now they are rapidly breeding with the hives full of bees. This certainly ought to be a test as to whether noise injures bees or not. We made no honey, it is true, last year, as it was a failure in this section everywhere; but if bees being in good condition is any proof that the noise and jar of the trains do not injure bees, then we have the proof that it does not.

Atlanta, Ga., March 5, 1887.

T. E. HANBURY.

A SWARM OF BEES IN A FENCE-POST.

I am very busy getting settled in our new home. I shall not have the many advantages for bee-keeping here that I did at Mohawk. I shall have to see what may be done in a location where little natural forage seems to be afforded. I shall report as I advance. I go to Mohawk for my bees about April 1st. It is about one month earlier here than there. I find I am not without bees here, even now. I notice one stock in a fence-post, and one in the roof of the house. Those in the post seem to have wintered well with one side open to the weather. This indicates a favorable location for wintering out of doors. I will report results after I get all at work in hives.

LYMAN C. ROOT.

Stamford, Ct., Mar. 21, 1887.

Why, friend R., you are starting a new idea in the way of hives. A fence-post would have one advantage—it would not be easily blown over by the winds. It has been suggested, that the rotten wood found inside of a tree has a special advantage in keeping the bees dry, and permitting the necessary ventilation. A rotten log is something like the old straw hive. Put a super over them filled with sections, and may be you can give us a good report, even if your present locality is not favorable, like your old one. We are glad to hear from you in your new home.

NOT GOING OUT OF THE HONEY BUSINESS YET.

I have 22 colonies in fair condition, from 25, fall count; and although I have had more than the usual average of losses, and less than the yearly estimated surplus, I can not help but believe there is truth in the following, copied from Prov. 14: 23: "In all labor there is profit; but the talk of the lips tendeth only to penury." As long as I can get 300 lbs. of pork for 100 lbs. of honey, and 100 bushels of wheat for 600 lbs. of honey, I am going to raise the honey and let others raise the pork and wheat, no matter if honey goes down to 3 cts. I believe the price of honey is comparatively too high, regardless of all the noise which has been made about its being ruinously low. I also believe that all the honey in the country can be easily disposed of by employing traveling agents of the right stamp, and sell direct to the consumer.

I. T. GOULD.

Corunna, Mich., Mar. 21, 1887.

HOW TO REGULATE THE VOLUME OF SMOKE IN A SMOKER.

I suppose you have often noticed, when using smokers, when the wood was dry and the smoker upright, it would burn too fast; and when the smoker was laid down flat it would go nearly out in a few minutes, sometimes entirely. Now, I have devised a plan to give the smoker any slant, and thereby control the draft. The plan is this: A corner clamp, with slot therein, and a small thumb-screw, is fastened to the corner of the bellows. A rod is run through the slot, and fastened by a slight turn of the thumb-screw. By adjusting the rod, the smoker-bellows may be held at any angle. I should like to know what you think of it.

O. F. WINTER.

Winterton, Sullivan Co., N. Y., March, 1887.

We never have any trouble with the Clark smoker, as now constructed, going out or burning too fast when not desired. If we want a great volume of smoke we turn the

Clark smoker on end. If we want it to die down soon, we lay it so that the barrel lies down in the grass. If we want it to strike a medium between these two extremes we lay it on the bellows, the same as seen in our price list. As you ask my opinion in regard to your invention, I will be free to say I think there is too much machinery about it for the average bee-keeper; and while I think it would accomplish all the results that you have claimed for it, yet I think that the same results, or nearly the same, may be obtained by the methods I have given above.

IN FAVOR OF EMPTY FRAMES WITH STARTERS ONLY.

I have read with interest your journal in regard to empty frames vs. empty combs. It may make some difference in different locations, but I have found in this section that I can get more surplus honey (in comb) from a swarm hived on 10 L. frames with only one-inch starters to get straight combs than I can a swarm hived on 10 L. frames full of empty combs. In the spring of 1886 I united two colonies with others, as they were weak in stores, so I could have the 20 frames to experiment on. The fore part of May, 1886, I hived a swarm in each of those ten-frame hives filled with comb. They made me no surplus. The last of May, 1886, I hived a swarm in the ten-frame hive with only starters of foundation. They filled the ten frames with comb, and gave me 24 lbs. of very nice comb honey. The swarms were alike, the three queens being nearly of the same age. I am convinced I can do better by hiving on empty frames than I can on those filled with empty combs—that is, box honey.

JOSIAH EASTBURN.

Fallsington, Bucks Co., Pa., March, 1887.

W. S. KALER DEFENDS HIS SWARMING-BOX.

I see on page 168, March No. of GLEANINGS, Mr. Felton, of Newtown, Pa., has misrepresented my swarming-box to some extent, and I would ask the privilege of explaining to your many readers the advantages of my box.

1. You do not stand and hold my box. Wait till the bees cluster; put the box under, then shake, and they cluster on the comb.

2. We use a frame of comb in the box, and the queen will alight and stay on it every time.

3. The bees will stay on comb in a box any reasonable length of time, and can be carried any distance, without the loss of bees.

4. The mode and cheapness of its construction, and the indorsements that it is getting from bee-men, proves its value to them. I make this statement to our brother bee-men who take GLEANINGS.

Andersonville, Ind., March 5, 1887. W. S. KALER.

LUTGEN'S METHOD OF CAUSING A BEE FILLED WITH HONEY TO EXPEL IT, A PRACTICAL SUCCESS.

I saw, in a recent issue of GLEANINGS, that, if you would catch a bee by its wings, and press the extremity of its abdomen on the thumb-nail, that, by the pressure thus exercised, you would cause the bee to regurgitate, or expel, in some way, the honey from the honey-sack. I put the matter to a practical test, and I assure you the test was in every way satisfactory. The experiment was conducted in the presence of Mr. A. S. Beach. As soon as the pressure was applied, the honey would

appear at the bee's mouth, in the form of a beautifully transparent globule. Mr. Beach pronounced the honey perfectly delicious—as fine, he said, as he ever tasted.

To see the little fellows fall on the ground before they reach the alighting-board, and panting for breath, reminds one of summer time. The bees are getting this honey from the maple, willow, and elm trees that grow on our creeks in this county. I live near the South-Carolina line, in Mecklenburg Co.

J. A. ARDREY, M. D.

Pineville, N. C., Feb. 17, 1887.

ARMSTRONG'S T SUPER—SOMETHING FURTHER FROM FRIEND ARMSTRONG.

Many thanks for kind words spoken in regard to my T super. I was thinking some of making it to have only one side to open; but then in case it should be reversed it would have to be reversed back again before the sections could be taken out, and the difference in the cost of construction would not be over 3 cents each, or $2\frac{1}{2}$, so I have concluded to let it be the way it is until the present craze of reversing is over. I think it would make a better case to have one side made whole, or in one piece, and, of course, our object should be to have every thing about our hives as simple, cheap, and practical as possible. That has been and is still my aim, and I know these are your sentiments. One good feature about my super is the double clamping wedges. They hold the sections so firmly together that we do not have to use such heavy T tins. Just examine this feature and see how firm they are held together. You could almost jump upon them with your feet, and not break through, and that with only $\frac{3}{8}$ of an inch base to the tins.

E. S. ARMSTRONG.

Jerseyville, Ill., March 5, 1887.

THE LARGE SWEET CLOVER OF THE SOUTH.

Referring to J. P. Caldwell's nameless plant (see GLEANINGS, Jan. 15, and Feb. 1, 1887), and mellot in the South, I will say I have seen, near Greenville, Alabama, the sweet clover in question in thousands of acres of pasturage and roadsides, gone wild, and as tenacious as the palmetto of the same locality. It grows quite large, so that stock which will eat it, brouse off only the branches. It is only a soft wood, hollow stem, never growing large, or more than six or eight feet high. It is good for bees when seasonable, but hot sun and drought render it useless. It blooms and seeds once a year. Now, our beautiful white-bark mountain shrub, blossoming every time it rains after a considerable drought, is a deciduous and perennial bush, with large grub of hard roots. It grows naturally in my yard among cedars among limestone. Because of its stinking smell when the leaves are mashed, some call it "polecat." Others name it wiesatch. I am told it is neither of these shrubs, which are well known out West, along with the great honey-plant, catclaw. Our sweet-flowering shrub grows much like privet, only with whiter exterior. Many call it the bee-bush, so much is it besieged by them for honey.

A. W. BRYAN.

San Marcos, Tex., Feb., 1887.

HIVING SWARMS ON EMPTY FRAMES, A SUCCESS.

I hived 10 swarms on empty frames the past season, and it was a complete success. I hived them on 8 frames, L. size, spacing them just 15-16 inches apart from center to center. I think this is very essential. There was but little drone comb, and the combs were very straight, except in one rather

small swarm the frames had fdn. starters. Sections were put on about two days after hiving. I do not have any trouble in getting the bees in the boxes when the frames are close together. I have tried it two years. My bees are mostly blacks or hybrids. All the bees in this locality are more or less mixed with Italians, I think, as yellow bands can be seen in about every swarm during the honey season.

Clinton, Ill.

HENRY WILLSON.

FIVE DOLLARS PER DAY AMONG THE BEES.

I am not discouraged with my experience during the summer of 1886 among the bees. I started with 13 colonies and increased to 36, except 3 lbs. of bees and 5 queens. I realized about \$5.00 per day for the time I spent with the busy workers, besides the increase. Nearly all of my bees are pure Italians, and they are as good as I want.

HOME-MADE COMB-BUCKET.

Some time ago I saw an account in GLEANINGS of a man who wanted legs to his comb-bucket, but you thought the cost would be too much. As brains are cheaper with me than dimes, I made one. I went to the tinner and got a sheet of tin 20x28 inches and bent it thus: [J] The sides are 10 inches high, and the bottom 8 inches broad; then I put in pine ends, one inch thick. I slip them in only $\frac{1}{2}$ inch, leaving it 19 inches long, 8 inches wide, and 10 deep, in the clear. Now, you have pine ends, and you can put on as long legs as you wish. A small strip of wood, nailed on the inside of the ends, supports the combs, and a strip of molding around the top protects the tin, and the bucket is done. The cover is made of wood. I got the tin for 20 cts., and the wood was out of the boxes in which goods were shipped to me. My bucket doesn't cost over 25 cts., and is robber-proof. You can put handles to it to suit. As good a way as any is to fasten two pieces of small cotton rope to the ends, like a bail, and both can be taken in one hand.

Arcadia, Kan.

S. C. FREDERICK.

BEES FLYING OUT IN WINTER.

Why do my bees fly when the weather is below freezing? I packed them in boxes 4 ft. wide x 12 ft. long, holding 18 hives. The bottom is 4 in. thick, and is stuffed with dry sawdust, and there is an opening of 2 inches for each hive. The hives are set close together each way, and 6 in. of clover chaff is in front, and the same on top. To-day I find the snow covered with dead bees, and roaring in the hive as they do in hot weather. Do you think they are too warm?

My crop of honey for last year from 42 colonies was 3600 lbs., and all June honey. I increased to 91. I sold one-third of the honey at home for 1 dollar per gallon, and will try to sell twice that amount this year at home. Bees had a good fly Jan. 26.

CHAS. BUDDINGTON.

Attica, Mich., Feb. 4, 1887.

I fear your bees are too warm, as you have them arranged. Can you not give a little more ventilation through the covering on top? I should prefer the entrances a little larger, to those colonies that seem to be making so much noise.

WHAT OUGHT WE TO EXPECT FROM TEN ACRES OF ALSIKE?

I had, in the spring, 20 colonies, and from the 20 colonies I received 840 lbs. of comb honey, and increased to 56. My honey was nearly all from red clover and motherwort. Though white clover was

doing its best at blooming, the bees paid very little attention to it. I got 15 and 18 cts. per lb.

There are, within half a mile of my bees, 10 acres of alsike clover, which was sown last spring, and it looks well. How much honey per acre does it yield on good ground? Did you ever notice bees getting pollen from dog-fennel? I have watched them load from it.

J. E. HENDERSON.

Roney's Point, Ohio Co., W. Va., Dec. 14, 1886.

I do not know, friend H., what 10 acres of alsike ought to do in the way of honey. Our facts and figures in this matter are very meager. I would say, at a rough guess, however, that 10 acres of alsike ought to keep 100 colonies of bees busy for perhaps three or four weeks; and during these three or four weeks they ought to store, say, 10 lbs. of honey each. This would make 1000 lbs. for the 10 acres. If anybody else can do better, let him try his hand at it.

NOTES AND QUERIES.

A SAMPLE OF FLORIDA HONEY.

I SEND you by to-day's mail a small sample of honey, made by those Florida "lazy bees." It has been extracted nearly 10 months. What think you of its keeping qualities? We "crackers" think it very good. I also inclose a twig from an orange-tree budded last spring. It is about 4 feet high.

W. L. DRUMRIGHT.

Sarasota, Manatee Co., Fla., Mar. 15, 1887.

[The honey is certainly beautiful, friend D. Are we to understand that it is from orange-blossoms? The specimen sent is exceedingly thick, of very fair color and beautiful flavor, although it would at once be called Southern honey, and perhaps might not bring as good a price as our white-clover honey of the North.—Thanks for the twig of orange-blossoms. The beautiful fragrance is still retained. If we could have some honey that tastes as these blossoms smell, would it not be an acquisition?]

TIERING UP: WORKING IN THE RAIN.

In regard to tiering up cases of sections, the trouble is that they get very brown on top, and, in the T super, I think they would get brown on bottom and top. How is this? I intend to try the Doolittle surplus arrangement, as described by Viallon, which protects the section all around. I propose to use them on zinc honey-boards, with wooden rims making a bee-space underneath.

TRANSFERRING IN THE RAIN.

Our experience has been, that a warm drizzly day is the best time to transfer bees. F. C. THOMAS.
Spring Valley, O., March, 1887.

COMBS MELTING DOWN.

Having received several letters from bee-keepers in the Southern States, asking how I prevent combs from melting down in the hot days of July and August, I wish you to please state that I do not know, for I never had a comb melt down yet. It gets hot here in Oyster-Creek Bottom. I use the Simplicity hive, two stories high, painted white, entrance open full width, and a rousing colony of bees in the same; and if that keeps the comb from melting, it is all I know about it. JOHN W. ROSS.
Phair, Texas, Feb. 1, 1887.

[Thanks, friend R. I believe the whole secret of not having combs melted down in hot weather is, to have all the hives painted white; and if the colony is strong, a full-width entrance is an additional

security. Here in the North (and we have some pretty hot weather too) we have all of our combs wired.]

HOW TO MAKE FIRE-KINDLERS OUT OF COMBS.

Your comb kindlings are good, but I will tell you how I prepare them. Take a one or two quart Mason jar, and fill with oil, say $\frac{1}{2}$ or $\frac{3}{4}$ full, and put the combs in whole. The part above the oil will do to handle without daubing the hands. After the kindlings are in, unscrew the cover and place the cob in front, and apply the match. Have some dry cobs ready, and place in the jar, and screw on the cover. One cob will burn 5 minutes, or longer.

Vernon, O., Jan. 7, 1887.

C. M. TRUNKY.

HOW SHALL WE KEEP COCKROACHES FROM HONEY?

Please tell how to get rid of cockroaches. A lot of rats could not be more destructive to comb honey, and not as nasty. They will crawl through almost any crack where the air can come through, then they multiply and grow fast. They fly from place to place. Coal oil will effectually cure the ants, but the cockroaches fatten on it—at least, sulphur and coal oil has not exterminated them for me.

D. C. McLEOD.

Plena, Ills., Feb. 14, 1887.

[As we have no cockroaches in our locality, we have had no experience with them. Can some of our readers who have had, offer a remedy?]

CAN THE BEES OF TWO QUEENS WORK TOGETHER HARMONIOUSLY?

In regard to the question asked on page 99, Feb. 1, by friend J. M. Cruickshank, I have tried such a hive as he describes, with the result that you give in your foot-note; viz., that, as soon as the honey-flow is over, the bees ball their queen in one swarm and then unite. FRANZ ZSCHOEIMITSCH.
Monticello, N. Y., Feb. 10, 1887.

TAKING BEES OUT FOR A FLY.

What do you think of taking bees out of the cellar on warm days, to take a fly? J. A. TUCKER.

Horace, Ills., Feb. 21, 1887.

[I believe the practice of taking bees out of the cellar for a fly is generally considered unnecessary. See what Dr. C. C. Miller has to say in regard to it in our last issue.]

WHAT KIND OF HONEY IS IT?

I send you by mail two samples of honey. Please let us know through GLEANINGS how the lighter compares with basswood honey in color and flavor; also tell us, if you can, what gives the other such a peculiar taste. It was the first we extracted last season. It was taken about the 10th of July. Milkweed, pleurisy-root, and sumach were in bloom at that time. We have no basswood here, and not clover enough to get a fair sample to judge by.

Brook, Neb., Feb. 22, 1887.

J. S. JOHNSON.

[Your lighter specimen compares very favorably in appearance with basswood honey, friend J.; but there is an unpleasant flavor to it—something like our autumn wild flowers—that would probably injure the sale of it. The taste of the other specimen is something I am not familiar with.]

THE ONE-STORY CHAFF HIVE A SUCCESS IN IOWA.

On p. 189 Ernest discusses the merits of one story chaff hives. I made ten of them three years ago, with Simplicity half-story covers. I have left them at the same place, winter and summer. They are all right yet. This is the third winter, and I haven't lost any colonies in them yet. J. N. SHEDENHELM.

Ladora, Ia., March, 1887.

HONEY TO BE NAMED.

Will you please tell me what kind of honey I send you sample of? I bought it in the central part of this State. Is it not California honey?

H. P. LANGDON.

East Constable, N. Y., Mar. 17, 1887.

[Friend L., the sample of honey is something I am not much acquainted with. I will explain to our readers that it is, when partially candied, of almost snowy whiteness. The flavor comes nearest to some honey I once saw in Michigan, said to have been gathered from a species of fireweed, if I remember correctly. There is very little flavor of any kind in it, and it is almost like simple syrup, although there is a slight taste that reminds one of the woods.]

REPORTS ENCOURAGING.

NEW COMB HONEY IN WISCONSIN ON THE 18TH OF APRIL.

I NOTICED an article in March 1st GLEANINGS, headed, "New Honey in Ohio on the First Day of May, and ended with, "Can any one beat that? I should like to hear from them if they can." Signed J. S. Barb, Bristol, Ohio. Well, I do not wish to boast, but I can beat this considerably, even in Wisconsin. I finished carrying my bees out of the cellar the 16th of April; and, as I reported before, the most of them were very weak; but I had one colony that was good. My bees are all weighed when they are put in the cellar, and again when they are taken out, and this one I weighed again on the evening of the 18th, and found a gain of 12 lbs. of fine honey from soft maple. I then put on surplus combs, and the weather turned cool, but still they stored about 20 lbs. more in April. This swarm was carried out the night of the 16th, and they were the lazy Italians too. If any one can beat this, let me hear.

Hillsboro, Wis., Mar. 10, 1887.

ELIAS FOX.

BEES IN ARKANSAS.

In Southwestern Arkansas my bees began to gather pollen about the 20th of Jan., from the maple and water-elm. There have been but five or six days since but that the bees have been gathering pollen or honey. I noticed in GLEANINGS, March 1, that some one said he had new honey the first of May. Well, if he were down here he could get some in March. I had some new surplus honey last year the 15th of March. My bees are the Arkansas brown bees—a very large bee. J. W. TAYLOR.

Ozan, Ark., March 5, 1887.

HONEY FROM THE HARD MAPLE.

Bees in the Tar-Heel aparies are booming. The bees have been "dropping" in right along the past week, and continue to do so at present. They are storing honey from the hard maples (we have no other here). Pollen has been stored plentifully since January 26th. It is an unusual thing here for bees to store so much honey from maple as they are now doing. Most colonies have plenty of young bees reared, and are already flying.

5—ABBOTT L. SWINSON, 71—70.

Goldsboro, N. C., Feb. 26, 1887.

THE FIRST SWARM.

Our first swarm came out this morning at 8 A. M. Temperature 58°. Bees are bringing in some honey from haw, willow, etc. Even our nuclei have been building comb for ten days—the first noticed—drone of course.

J. W. K. SHAW & Co.

Loreauville, Iberia Parish, La., Mar. 1, 1887.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

BLUSTERING WEATHER.

AT this writing, March 29, we are unable to give any thing definite as to the condition of our bees. There has not been a suitable day for examining them for the last two weeks. As we felt sure that they were not running short of stores, we did not peek under the cushions and "heft" the frames as we could have done, in a manner before described under this head. Had there been one or two days warm enough, we should have thoroughly gone through the apiary, solely for the purpose of ascertaining whether any more foul brood had developed; but every day has been so chilly that we hardly thought it best to pull out and examine every comb in the apiary. It might be disastrous to some of the weaker colonies. Besides, if there is a possible case of foul brood during this cold weather when no bees are flying, it could hardly do any harm.

To-day, while sitting here it is cold and blustering outside. The temperature this morning was 12 degrees above zero—rather cold for us at this date.

OUR OUT-APIARY.

We have already had some correspondence with a party with reference to establishing an out-apiary. The location is five miles from Medina, and we are informed that there is an abundance of alsike sown within the immediate vicinity. It does not, however, have very much basswood near by, owing, probably, to the fact that there is a sawmill half a mile or so distant. In fact, I might say it is quite difficult to find any considerable amount of basswood in any one location within a radius of five or ten miles of Medina. Farmers around here have been in the habit of cutting up their basswood logs for the "Home of the Honey-Bees," to be cut up into sections. In the words of that homely expression, we have been "cutting off our own nose," seemingly. However, we will not take space to discuss here whether or not bee-keepers as a rule had better cut up the basswood-trees, or let them remain for the bees.

As has been stated, this out-apiary will be used for the purpose of testing more thoroughly some of the modern appliances for the production of comb honey. Our own home apiary for the last ten years has been devoted almost exclusively to the rearing of queens; hence we realize the necessity, not only for our own benefit, but for the benefit of our customers, of testing every thing that comes up—in short, as far as it may seem feasible and practicable, to continue more thoroughly the work of an experimental station.

Later.—Since writing the above we have had quite a material change in the weather. The bright sun is shining, and the glorious (? "Medina mud" has come. There is still a cold breeze this afternoon, and scarcely a bee is flying; therefore we can not, as we had hoped to do, report in regard to foul brood.

TOBACCO COLUMN.

AN INCIDENT; HOW THE FUMES OF TOBACCO FROM THE BREATH OF A USER CAUSED SICKNESS IN A COMPANION.

AS I was reading George B. Morton's article on the use of tobacco, and how disagreeable the smell of the breath is of those who use it, it reminded me of a little experience I had when a boy. My father sent me to mill, and a neighbor rode along. He was a young man, but he used a great deal of tobacco. I stood it as long as I could, then I made some excuse and got in the other end of the seat, so the gentle breeze was in my favor. Pretty soon we overtook an old fellow, and asked him to ride; and as I was a little fellow I had to sit in the middle, and it so happened that he was just about as full of whisky as the other was of tobacco, and about this time we came between two pieces of timber where there was no air stirring, and I soon got so sick that I vomited, and could not drive, and had to lie down in the back end of the wagon. Every thing was swinging round and round. Oh dear! how sick I was! and really I thought then it would kill me. They were alarmed, and asked me what was the matter. I told them I guessed I was drunk on tobacco and whisky, riding between them. I did not get over it in several days, and it makes me feel queer now to think of it. Do all you can in this direction, and may God bless you!

JOHN BARLOW.

Sac City, Ia., Jan. 24, 1887.

My wife has quit using tobacco, and says you may send her a smoker. If she ever smokes any more I will pay you for it. WM. D. TITCHENELL.

Pleasant Hill, W. Va., Jan. 13, 1887.

Please accept this as my pledge to give up tobacco. I promise to pay you for the smoker if I use the weed again. J. A. BROWN.

Bryantville, Ky., Feb. 1, 1887.

PA'S PROMISE.

Pa says if you will send him a smoker he will never use any tobacco in his life, and will use all his influence against its use. F. A. THOMAS.

Morrilton, Ark., Jan. 23, 1887.

ONE WHO POINTS OUT THE WAY OF LIFE QUILTS THE USE OF TOBACCO.

My brother-in-law, George Malmsberry, has quit the use of tobacco, and says he will agree to pay ten dollars if he ever uses it again. He is a minister of the gospel, so if you think he is entitled to a smoker, send one to him. G. BRIGGS.

Garfield, O., Jan. 19, 1887.

A USER FOR 30 YEARS.

I was a habitual chewer for about 30 years. It has been some little time since I discontinued its use. If you see fit to send the smoker to my address, I agree to give you \$1.00 if I use tobacco again.

F. A. KINNEAR.

Lindenville, O., Jan. 27, 1887.

HAS USED IT FOR 20 YEARS.

I understand that you give a smoker to each tobacco-user, if he quits the bad habit. I have used tobacco for about twenty years; and I will quit using it in any form, if you will give me a smoker; and if I ever use the weed again I will pay you for the smoker.

W. J. HALTON.

Jordan Village, Ind., Jan. 8, 1887.

THE EFFECT OF TOBACCO ON THE HEALTH.

I have been considering for a long time what to do about quitting tobacco. To me, smoking, although a filthy habit, is a comfort; but I know it injures me. Five or six years ago I smoked so much that I became very nervous and debilitated, with a good dose of dyspepsia thrown in. Although much better, I am not over it yet. Now, as I am getting ready slowly to start in bee-keeping, I think a smoker will do me more good than smoking; therefore on receipt of a smoker, or your promise to send one, I will pledge you my word that I will use no more tobacco at any time in the future. If I do break my pledge, I will forfeit the price of smoker.

T. JENNINGS.

Rye, N. Y., Jan. 18, 1887.

The following comes to hand later:

I received the smoker yesterday, and feel much pleased with it, and thank you very much. I hope I shall be deserving of it. I was working in the barn, and just thinking about taking a smoke, when my boy came in with the smoker, and said the postmaster told him he thought it must be a patent rat-trap. As soon as I saw it I knew what it was, and came to the conclusion I had had my last smoke. So now I am in for it, and hope I shall be able to hold out.

T. JENNINGS.

Jan. 29, 1887.

We hope sincerely it will be your last smoke, friend Jennings.

HAS USED TOBACCO 45 YEARS, AND NOW TELLS HOW HE WAS INDUCED TO QUIT.

Friend Terry forwards the following good letter which he received. As it may help some brother who may be still a slave to the use of tobacco, we give it to our readers:

Friend Terry:—I have been a constant reader of GLEANINGS for the last five or six years past, and within the last couple of months I have noticed several very able and interesting articles from your pen. One of the articles appeared in the above journal, Dec. 15, 1886, and was headed, "Friend Terry on Tobacco." I must confess that the above article struck me very forcibly, and presented the subject in a somewhat new light to me. I had been using the weed for about 45 years, having contracted the habit when about 15 years old, and have used it ever since, without hardly stopping to consider at least the impropriety of the habit, until I became a reader of GLEANINGS, and ever since that time I have been somewhat under conviction. I felt that the use of the weed, to say the least about it, was a very filthy and expensive habit, and unworthy to be indulged in by any Christian being, and a habit in whose favor not one good word could be said. When that is the case with any thing, it should go down to oblivion never to rise again, and *there* is just where my pipe and tobacco have gone. The reading of your article above referred to did the business, and settled the question in my case. It was the last feather that broke the tobacco camel's back. I sincerely hope that it may have the same effect upon a great many more who are indulging in the same habit. The first thing I did after reading your article was to get up and lay away the old pipe and tobacco for ever. This was on the 28th of Dec., 1886, and I have not tasted the vile stuff since; and, by the grace of God, I never will. Now, you and Mr. Root may think that I was a pretty tough customer to convert, if it

took some five or six years of preaching, and, to succeed in the end, a double-handed dose. Well, friend Terry, I will admit that it looks a little that way; but then, I know that you will also admit that a bad habit of 45 years' standing is not an easy matter to break away from. All the satisfaction that I can see, that you and brother Root can get out of my case, will be that you can add the name of another convert to your list and the Tobacco Column; but I do not want you to send me a smoker nor potato-box. If I can not keep the pledge without them, I am afraid I could not with them.

G. W. HARRISON.

Wharton, Wyandot Co., O., Feb. 8, 1887.

MYSELF AND MY NEIGHBORS.

Who is my neighbor?—LUKE 10: 29.

WHY did God give us neighbors? I presume the answer would be, that he gave them to us to make us happy. Suppose, however, we change it about and say that God gave us our neighbors that *we* might make *them* happy. How would that do? We are almost unconsciously so much in the habit of being selfish that we answer questions from a selfish standpoint. In a sermon a Sunday or two ago, our pastor said that everybody is our neighbor when it is in our power to do him good, or to help him. If this be true, then when we are commanded to love our neighbors as *ourselves*, we are at all times to hold ourselves in as much readiness to do good to those we meet as to do good to ourselves. There is an unexplored region in this line, dear friends. You may be a little surprised to hear me speak of an unexplored region when so much has been said about the golden rule. Very likely you feel as if the subject had been exhausted. Well, it may have been exhausted so far as talk is concerned, but it has not in putting the words of our Savior into real practice. For instance, a few days ago I stepped out on the front walk and saw a man a little distance away who seemed as if he wanted to speak to me; and yet when I came near him he turned away as if he really did not want to see me after all. I finally spoke to him when he came up. His first words were:

"Mr. Root, I hope you haven't laid any thing up against me because I didn't do exactly as I agreed to."

"Why, my friend, I don't know what you mean. Your face looks familiar, yet I can not now recall any transaction in which you did not do as you agreed."

"Why, it was about those potatoes. I told you you might have them; but I met a man afterward who offered me five cents a bushel more, so I let him have them, and went off home without saying a word to you about it."

I was obliged to smile when I told him I had entirely forgotten the whole transaction. In any case, however, I assured him that I felt glad to know that he had been able to get a larger price than I offered; and he looked quite happy when I told him further, that, whenever a chance offered to

get a better price than I could afford to give, by all means to take it; and I assured him that I always felt pleased to see farmers get a good price for their produce, no matter whether it inconvenienced me or not. Since then I have made it a point, when offering a price for any such product, to add, "Now, my friend, if anybody else offers you more than I have offered, take it, by all means, and I shall be pleased for your sake."

Now, please do not understand, friends, from what I have said in the above that I would encourage anybody in breaking a fair and square business promise. If I had engaged a load of produce, and made calculations on using it to fill special orders, and the man should fail to fulfill his promise because he had a better offer, it would be quite a different matter. In the above I have had in mind only small produce, such as farmers are constantly bringing in—something I could use or get along without, with no inconvenience. In such cases I enjoy giving them standing permission to take up with a better offer whenever they chance to get it, and I do the same thing with the hands in my employ. Whenever any one of them gets a better offer than I am able to make, I *make* myself feel glad for his sake.

Our place of business is located on the way to town, and almost every day somebody brings in apples, potatoes, honey, maple sugar, and other things, to sell. After looking them over I decide what amount I can afford to pay. Then I tell them pleasantly that, if they choose, I am quite willing they should go up street and see what offers they can get there; if they can not do any better, bring them back to me. This way of doing business, however, seems, to surprise our rural friends, and a great many times I have noticed their smiling faces as they came back, telling me they had got a half a cent a pound or five cents a bushel better than my offer. Now, they sometimes have something I really want, and probably are not satisfied with what I think I can afford to pay them for it; and therefore I feel a little sorry to have them drive off. Self whispers, "Now, I really want that lot of strawberries; and I am afraid, if he goes away, somebody will offer him a little more, and I won't get them at all." At such times, however, I bid self get out and get down out of the way, just as I would a little unmannerly cur that was hanging around, watching for an opportunity to do some mischief. If the man comes back, and says I can have the lot, for he could get no better price, I am happy; and if he comes back saying he got a cent a quart more than I offered, I am happy also even then, for he is my neighbor; and whatever helps my neighbor *helps me*. One old farmer spoke to me one day about it. Said he, "Mr. Root, I have made up my mind after this to always give you the first chance, for I shall always remember the time when you told me to take those apples up street and do the best I could with them. I did as you said, and sold half of the load for a little better than you offered, and then you took the rest at just what you said you would. I tell you, it makes a man feel as if *one* man

who is doing business so was interested in somebody besides himself."

There is another way in which we can help others in our daily deal. It is quite a hard matter to decide, many times, just what you can pay for produce, especially the first maple sugar, the first ripe apples, or new potatoes, etc. I often do this way: If my neighbor wants more than I can afford to pay, I say to him, "I will pay what you ask, providing you will help me out if I don't succeed in getting my money back;" or, "I will take them at such a price; and if I get rid of them easily I will pay you five cents more per bushel." This is having the matter in my own hands, I know; but in such cases I am always very anxious to be able to give my neighbor a little more when I meet him next time, if it is a possible thing. You see, you shoulder the responsibilities together in this way. It would be no pleasure for me to do business, if I thought the man with whom I did business was selling at a loss.

Now, then, friends, we are coming to real business, and I generally have some sort of business in mind when I start out to write these neighborly talks. We have been selling the Parker machine for fastening starters in section boxes, for three or four years; and for general purposes we do not seem to get hold of any thing much better. At the time friend Parker gave me the idea, I told him I thought it would be worth to us \$5.00. When it began to have quite a large sale, however, I told him I guessed it was worth \$10.00 more; and now that it is having a still larger sale, I think he ought to have about \$25.00 in addition to what he has had already. In the same way, I gave Norman Clark, of Sterling, Ill., \$25.00 for the cold-blast smoker. As it has turned out, I don't think I gave him enough; and in talking over the matter we have concluded we owe him, in justice, about \$100 for his splendid invention in the way of smokers. Neither of these friends has asked for any more, and I don't suppose they ever thought of receiving any more; but for all that, it is a pleasure for me to give it to them. Friend Peet, who gave us the queen-cage, was also satisfied with \$25.00 I paid him some years ago; but as it still seems to receive the preference, I think we owe about another \$25.00. Friend Klinitz' queen-catcher is also having a very large sale, and is giving universal satisfaction. At the time he sent it I gave him \$5.00 for the idea, and I think he is now entitled to about two more fives, or \$10.00 more, which we place to his credit. And we hereby take pleasure in telling the friends mentioned, that the above sums are placed to their credit, awaiting their order.

Now, I hope none of the friends will criticize my method of purchasing inventions. It seems to me a duty, and I enjoy doing it. Very likely I am notional and peculiar about new inventions; but I have so many times paid money for things that were used for only a short time, or never used at all, that I begin to feel as if I did not want to offer very much for any thing again, until it seems to me to stand the test of months and years of daily use.

"THE PRODUCTION OF COMB HONEY."

THE above is the title of a little book of 45 pages, by W. Z. Hutchinson. It is written in friend H.'s happiest style, and sums up the whole matter of his method of getting comb honey, by obliging the bees to build worker comb in the brood-frames while they are storing honey in the sections, said sections being filled with foundation. The principle consists in contracting the size of the brood-nest so as to force bees into the sections. The queen is kept below by the queen-excluding honey-boards. By much the best way of contracting the brood-chamber is by means of Heddon's half-depth brood-chambers. The brood-nest is then contracted in size, but at the same time there is brood right under all of the sections. The result is, having all the honey above in marketable shape, and all the brood and pollen below. It is, in fact, much the same as the L. frame, with sealed honey in the upper half and brood and pollen in the lower half. The two halves are capable of being separated. We can mail the book to any address for 25 cts.; 10 for \$2.00.

OUR FRIEND THOMAS HORN.

AS claims have pretty nearly stopped coming in, we have decided to wind the matter up and close the books, it having been eight weeks since we first asked to have them sent in. Eighty-five persons have reported, and the total amount of money now claimed is about \$438.62. As the number of individuals is so large, and the amounts of money are mostly so small, I have decided to forward all letters to friend Horn, keeping for future reference the addresses of the parties, and the amount of money claimed. The greater part of the claims are for money sent, for which nothing was ever received. There are, however, a few, and some of them tolerably large amounts, where the order was partially filled; but we hope that friend Horn and the purchaser can agree on what amount is still due. After having agreed, friend Horn is to send his note, payable in two years, or as much sooner as he can make it. He then proposes to take up these notes as speedily as possible. In case there can not be an agreement in regard to the amount due, I would suggest letting some disinterested third party decide it. As fast as Mr. Horn's creditors are satisfied, I should like to have them report directly to me, that we may publish their names for Mr. Horn's encouragement.

PROTECTING SECTIONS OF HONEY IN STOUT MANILLA OR CARDBOARD CASES.

OUR enterprising friend, H. R. Wright, of Albany, N. Y., the man who has pushed the ten-cent package of comb honey so energetically, mails us a sample case, or carton, made of very heavy stout manilla paper, to be slipped over the section as soon as it is taken from the hive. To allow the purchaser to see the honey, an opening two inches in diameter is cut through the center of each side of the box. This paper case is stout enough to hold the section tightly together, thus entirely preventing the corners coming apart in shipping, or when pulled from the case. Friend Wright says it also obviates the necessity of scraping off the propolis, for the paper case entirely covers it, and this case need never be removed until the honey is taken out of its covering, and put on the table. The envelope also covers up all vacant spaces and cells, and protects from leakage and breakage. It makes the sections look all exactly alike, covers up all soils and stains, makes the packages neat, clean, and uniform in appearance, and yet with all these advantages it costs only half a cent for each pound of honey. Friend Wright proposes to furnish these envelopes at cost, and thinks it will be the means of increasing the sale of honey a hundred fold. We presume samples are furnished free on application, although friend Wright does not say so in his circular.

AN ENCOURAGING FEATURE FOR SEED-GROWERS AND OTHERS.

THERE has been so much lamentation over the low prices offered for almost all rural products that it is a little bit pleasant to talk about advance in prices. Last season, after we had put in all the peas we needed for market, I took all that remained in stock after orders had ceased coming, and sowed them for the purpose of raising seed. They did finely in the fall of the year, and we raised a lot of seed, apparently as nice as that purchased from our seedsmen. One patch of Stratagem was, by neglect, never gathered. One reason why we did not take the time to do it was, that I concluded I could purchase what seed I needed, almost as cheaply as I could fuss to put up two or three bushels. It now transpires that the Stratagem, American Wonder, and Yorkshire Hero, are wanted everywhere; and it is a question whether some of them can be found at any price. The same is true of the best kinds of sweet corn, Golden-wax beans, and many other of the new leading vegetables. The grower who last year put in a good lot of something that he knew was good, has now the opportunity of securing a price that will pay him handsomely. We find this state of affairs constantly occurring. One who has a nice crop in stock of a really good thing, every little while finds a scarcity in the market, and then he receives his reward. It is a good deal so with honey. It is expensive to keep many things over, waiting for better prices, and sometimes it is a little dangerous; but the prudent man remembers past experiences, and prepares himself to meet emergencies.

CONVENTION NOTICES.

The bee-keepers of Wisconsin will hold a convention at Hingham, Sheboygan Co., May 5, 1887. MRS. H. HILLS.

The semi-annual meeting of the Southern Illinois Bee-keepers' Association will meet in the Court-house in Benton, Franklin Co., Ill., April 30, 1887, at 10 A.M. All are invited. F. H. KENNEDY, Sec.

CIRCULARS RECEIVED.

The following have sent us their circulars since our last issue:

- S. H. Blosser, Dayton, Va., an 8-page list of apianian supplies.
- Charles F. Uhl, Millersburg, O., a 4-page circular of bees and queens.
- Simon P. Roddy, Mechanicsville, Md., a 2-page list of queens and bees.
- Mrs. Oliver Codd, Sherburne, N. Y., a 6-page circular of bees and queens.
- S. C. Perry, Portland, Ionia Co., Mich., a 6-page price list of bees and queens.
- S. Valentine & Sons, Hagerstown, Md., a 34-page list of apianian supplies.
- E. H. Ricker & Co., Elgin, Ill., a 6 page (large size) list of nursery supplies.
- Robison & Gillette, Willoughby, O., a 4-page (large size) circular of berry-baskets.
- E. W. Pitzer, Hillsdale, Ia., a 10-page circular of bees, poultry, hives, sections, etc.
- Hayward & Stratton, East Pepperell, Mass., a 10-page circular of apianian supplies.
- Martin & Macy, North Manchester, Ind., a 24-page circular of bee-supplies and poultry.
- Jos. W. Newlove, Columbus, O., a 12-page circular of apianian supplies and small fruits.
- Charles D. Duvall, Spencerville, Md., an 18-page circular of bees and high-class poultry.
- John A. Thorton, Lima, Ill., a 6-page price list of bees, queens, poultry, and a few apianian supplies.
- G. H. Knickerbocker, Pine Plains, N. Y., a 4-page (large size) circular of bees and queens. The strain of bees which Mr. K. advertises are those formerly owned by L. C. Root.
- Charles Stewart, Sammonsville, N. Y., an advertising card of comb foundation, extractors, smokers, etc. Mr. S. uses one of J. H. Martin's chrono cards, which we noticed before.
- J. B. Mason & Sons, Mechanic Falls, Me., a 24-page (large size) catalogue of bee-keepers' supplies. Messrs. M. & Sons are the editors of the "Bee-keepers' Advance," which we have before mentioned in our columns.
- T. G. Newman & Son, Chicago, Ill., a 34-page circular of every thing necessary for the apianian. Mr. Newman advertises as usual a large collection of supplies, and we are always glad to recommend him to our bee-friends.
- Joseph Nysewander, Des Moines, Iowa, a 30-page circular of apianian supplies. We notice that Mr. N. has recently bought out Mr. J. M. Shuck, so that all needing reversible hives and reversible supers, as formerly made by Mr. S., will now obtain them of our friend Mr. Nysewander.
- George Neighbour & Sons, 149 Regent St., Holborn, London, England, send us a 70-page (large size) circular of every thing needful for the apianian. As usual with price lists received from England, we notice a very large collection of hives. Besides hives and implements constructed in England, we notice that Messrs. N. & Sons offer for sale those made after the American patterns. A perusal of this circular will give one a pretty fair idea of the status of bee-keeping in England.

SPECIAL NOTICES.

WANTED, JANUARY AND FEBRUARY NUMBERS OF THIS YEAR.

UNTIL further notice we will pay 10 cts. each for either of the above numbers; and those of our subscribers who failed to get them, and who still want them, may have them at the same price; that is, we will pay 10 cts. each and sell for 10 cts. each, for the sake of accommodation, paying postage besides, ourselves.

ALSIKE CLOVER.

THERE has been such a demand for seed of the above clover, that the market is practically exhausted. Our prices for the present will be the same as before the last decline; viz., \$8.00 per bushel; \$4.25 per half-bushel; \$2.25 per peck, or 18 cts. per lb. By mail, 18 cts. per lb. for bag and postage. Now, in giving the above prices we are obliged to say that there may be a still further advance before your order reaches us. While this advance in price makes it hard for those who are obliged to buy, it is a good thing for those who have provided themselves with a stock of seed to meet the emergency.

THE NEW JAPANESE BUCKWHEAT.

THE demand has been so much greater than my expectations, that I have sold not only the one bushel first purchased, but five additional bushels; and by taking ten bushels more I have got it at a price so I can furnish it at the following reduction; \$6.00 per bushel; \$1.75 per peck; per half peck, \$1.00; 1 lb., 25 cts.; ¼ lb., 8 cts. If wanted by mail, add 5 cts. per ¼ lb., or 18 cts. per whole pound, for bag and postage. For all we know in regard to the new grain, see March No., page 167. The fact that it is so much larger in size is of itself quite an inducement to give it at least a trial on a small scale.

KIND WORDS FROM OUR CUSTOMERS.

PACKING SO WELL.

The seeds you sent me came up. Soon after, I sent you an order for 10 Simplicity bee-hives. Please accept thanks for packing my goods so well. Trinity, Tex., Mar. 6, 1887. WALTER A. MARTIN

A PERFECT BEAUTY.

I received the goods you sent, all in good order. Your method of packing is efficient. The queen you sent is a perfect beauty. She was on the way six days, and there wasn't a single dead bee in the cage when received. Thanks for promptness. Derden, Tex. J. OFFUTT.

TEN STANDS FROM ONE POUND OF BEES RECEIVED LAST MAY.

I received those sections to-day, which you shipped the 21st. They are all right. I am well pleased with them. They came in nice order. I have not examined my bees for some time; they were all right then. I have ten stands from the pound of bees and queen I received from you one year ago last May. R. P. WARWICK.

Dayton, Tipp. Co., Ind., Feb. 28, 1887.

PERFECT SATISFACTION.

Those sections I got of you gave perfect satisfaction in every way. I order all my goods through Mr. Elias Cole, and have for years past. I ordered 1000 sections, 4 3/4 by 6 inches, and I am perfectly satisfied. I will call on you again. I have 69 swarms of bees. I obtained 1200 lbs. of comb honey last season. I have lost but one swarm of bees in three winters. E. DIFANEY.

Norton, Ohio, March 14, 1887.

WORTH A DOZEN OF THE OLD ONES.

The fdn. mill arrived here all right, March 19th. Express charges were \$1.25. I am well pleased with it, and also your promptness in filling the order. I was in a hurry for the mill, that is why I ordered it by express. I had counted the cost before sending for it. The mill is worth a dozen like the old one, in my estimation. I have made over 50 lbs. of fdn. on the new since it came, and have not had as much trouble with it as I did in making one pound on the old one. FRANK L. ROWLEY.

Sycamore, Ill., March 21, 1887.

200 COLONIES OF Choice Italian & Albino Bees

FOR SALE AT GREATLY REDUCED PRICES.

Also a full line of Bee-keepers' Supplies. **COMB FOUNDATION** from choice select yellow beeswax a specialty, at very low rates, both wholesale and retail.

NEW POULTRY and FRUIT BOOKS

Free

The Publishers of **Farm and Home**, a semi-monthly Agricultural and Family Journal published at Springfield, Mass., make the following unprecedented trial offer, in order to introduce **Farm and Home** into thousands of new homes, being confident that once a subscriber you will not do without it.

The regular price of **Farm and Home** is 50 cents a year, but on receipt of **30 cents** in stamps or money we will send **Farm and Home** the rest of this year, and in addition will send **free** and **postpaid** two new and valuable books, the "**Practical Poultry Grower**" and the "**Practical Fruit Grower**." These books will be worth ten times the money paid to any one interested in poultry or fruit.

The Practical Poultry Grower

is the **Most Complete, Most Practical** book of the kind ever published.

A FEW OF ITS MANY FEATURES:
GENERAL CARE AND MANAGEMENT, Directions for having early chicks, etc.

ARTIFICIAL POULTRY RAISING is fully treated by **JAMES RANKIN**, whose 16 years' experience in the business make him an authority. Tells how to construct home-made incubators.

FEEDING POULTRY for Eggs, Meat and breeding.

WINTER CARE. This chapter tells how to make hens lay in winter as well as in summer.

PRESERVING EGGS. This chapter alone will enable you to make money by holding eggs for a higher market.

POULTRY ARCHITECTURE. Illustrations of new and practical poultry houses. Composed entirely of **NEW AND PRACTICAL MATTER** from actual experience. This chapter alone contains more valuable information, plans, etc., than several of the treatises of poultry architecture that are sold at 25 or 50 cents each.

**A NEW BOOK,
Offered Only by Us.**

The Practical Fruit Grower

is a **Standard Work** by a **Standard Authority**, being written by **PROF. S. T. MAYNARD**, of the Massachusetts Agricultural College. It contains the results of years of **successful fruit growing**. An **INVALUABLE** AID TO EVERY ONE interested in fruit culture.

SPECIAL 15-DAY OFFER.

"Money Crops" FREE! To every one accepting the above offer within 15 days.

we will send in addition **"MONEY CROPS—HOW TO GROW AND HOW**

TO SELL THEM," a book of great value to every gardener and Farmer. Given

concise, plain, practical, common-sense and detailed directions for

planting, cultivating, harvesting and marketing nearly 100 Money Crops.

Under this offer every one sending **30 cents** within **15 days** of the receipt of this paper, will receive **Farm**

and **Home** twice each month for the rest of the year **1887**, and

3 GOOD FARM BOOKS FREE!

MONEY REFUNDED IF NOT FOUND JUST AS REPRESENTED.

Farm and Home is acknowledged by all who know its value to be the **best paper of its class**, If you are interested in the **Farm and Garden, Live Stock, Fruit, Poultry, Bees, Plants and Flowers**, the practical hints in any one number will be worth to you more than the money required.

It is as good for the **WEST** as the East, being **National in character and circulation.**

AN EXTRA SET OF BOOKS and copy of **Farm and Home** given for a club of **5 at 30 cents each.**

Address, mentioning this paper,

THE PHELPS PUBLISHING CO.,

Remit with Postage Stamps, Postal Notes, or otherwise.

Springfield, Mass

The three books contain nearly **400 pages**, or as many as other books that sell for **\$1 each**. Such an opportunity to obtain good reading has never before been offered.

Belleville, St. Clair Co., Ill.

WANTED.—To exchange for extracted white clover or basswood honey, or bees, a new foot-power saw. Write for particulars.
7tfdb W. S. WRIGHT, Battle Creek, Mich.

WHAT am I offered in exchange for a high-scoring Wyandotte cockerel, of the "Poquanock" strain?
W. H. OSBORNE, Chardon, Ohio.

WANTED.—To exchange Italian bees or bronze turkey-eggs for a Canary bird singer and cage.
7d GEO. W. BAKER, Milton, Wayne Co., Ind.

WANTED.—To exchange bees by the pound or full colonies, queens, comb fdn., eggs for hatching from L. Brahmas and S. S. Hamburgs, for sections, Jersey cow, American Merino sheep, or offers.
6-7-8-9d J. P. STERRITT, Sheakleyville,
Mercer, Co., Pa.

WANTED.—To exchange for beeswax, one foot-power saw. Also wanted, a good Mexican saddle and bridle, for sections or other supplies.
6-7d C. A. GRAVES, Birmingham, Ohio.

WANTED.—To exchange a Wilson's bone-mill, new, O. K., for 4 Italian dollar queens in July.
7d A. MOTTAZ, Ottawa, Ill.

WANTED.—To exchange 80 colonies of bees in chaff and Simp. hives, of 10 wired fdn. frames each, for some good land near by. Apply at once.
7-8d JAS. H. ANDRUS, Almont, Mich.

WANTED.—To exchange Wyandotte eggs, pure ground bones and shells, and Gregg raspberry-plants, for comb foundation.
7-8-9d A. A. FRADENBURG, Port Washington, O.

WANTED.—To exchange section boxes, 4-piece dovetailed, $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$, price \$4.00 per 1000, for a Planet Jr. seed-drill and cultivator, or a comb fdn. mill (a 10-inch mill preferred).
7d F. T. HALL, Lochiel, Dunn Co., Wis.

WANTED.—To exchange metal cornered, wired frames (Simp.), ready to hang in the hive, filled with foundation, for Italian bees and queens.
7-8d R. B. BONEAR, Cherry Ridge, Pa.

WANTED.—To exchange Barnes foot-power saws and bees, for steam-engine, honey, or beeswax.
7-12db C. W. & A. H. K. BLOOD, So. Quincy, Mass.

WANTED.—To exchange Cuthbert raspberry roots for a double-barrel 12-gauge breech-loading shot-gun, or a female ferret, or beeswax.
M. ISBELL, Norwich, N. Y.

WANTED.—A young man of some experience, to take charge of an apiary of sixty colonies of bees, either on shares or for wages. Address
7d J. P. CONNELL, Box 132, Hillsboro, Texas.

Wanted. A good bee-keeper to take charge of my apiary of 12 colonies, on shares.
ROBERT BLACKLOCK, Killgore, Carter Co., Ky.

WANTED.—Competent assistant in apiary for summer.
DR. THOM, Streetsville, Can. 6-7d

WANTED.—A steady man to work small apiary and garden. Correspond with J. T. DUEWARD, Seneca, Wis.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet 't is often times quite an accommodation to those who can not afford higher-priced ones.

I have about 30 hybrid queens, reared mostly from imported queens, but have proven hybrids. These I will sell, during April, at 50 cts. each; May, 37 $\frac{1}{2}$ cts. each. June and after, 25 cts. each. June and after, per half-dozen, \$1.25. Per dozen, \$2.25; per two dozen, \$4.00.

GEO. W. BAKER, Milton, Wayne Co., Ind.

I shall remove 6 young mismated Italian queens, about the last of April. Who wants them at 50 cts. each?
MISS A. M. TAYLOR,
Box 77. Mulberry Grove, Bond Co., Ill.

Twenty-five pure Italian queens, mated with black drones, at 50 cts. apiece, now. Safe arrival guaranteed. Three black queens at 25 cts. apiece.
S. H. COLWICK, Norse, Bosque Co., Texas.

A few good hybrid queens, in April and May, at 50c each.
PELHAM & WILLIAMS, Maysville, Ky.

GIVEN AWAY.

We will send free by mail one of our latest improved drone and queen traps to each yearly subscriber for the *AMERICAN APICULTURIST*. Price \$1.00 per annum. Sample copies free. Send the \$1.00 in common letter at our risk.

Address *AMERICAN APICULTURIST*,
7tfdb Wenham, Mass.

TESTED QUEENS, in April and May, at \$2.50 each.

HONEY COLUMN.

CITY MARKETS.

MILWAUKEE.—*Honey*.—The demand for honey is quite fair for good qualities, either comb or extracted. We quote:

Choice white 1-lb. sections, 11@12
" " 2-lb. " 10@11

Dark, not wanted.

Extracted, white, in bbls. and kegs, 6@6½
" " in tin pails, 6½@7
" dark, in bbls, 4@4½

Beeswax, 25c. A. V. BISHOP,
Mar. 28, 1887. 142 W. Water St.

CHICAGO.—*Honey*.—Season is quite far advanced for comb honey, and sales are in a small way. Prices are easier than on last quotations, still we try to get 12@13c for the fancy lots, and there is not much of that grade. Extracted, about the same as last quotation. Beeswax, 25c.

R. A. BURNETT,
Apr. 9, 1887. 161 So. Water St., Chicago, Ill.

CLEVELAND.—*Honey*.—The market has been a little more active of late and there has been a fair demand for best 1-lb. sections of white honey at 11@12. Second quality continues dull at 9@10. Extracted, 5@6. Beeswax, 25c.

A. C. KENDEL,
Apr. 9, 1887. 115 Ontario St., Cleveland, O.

COLUMBUS.—*Honey*.—White clover in comb in good demand at 14@15c. California, none in market. Extracted, white clover, 10@12c. Good white-clover honey is scarce in this market and sells readily at quotations.

EARLE CLICKINGER,
Apr. 9, 1887. 117 South 4th St.

CINCINNATI.—*Honey*.—No change since our last quotations. Demand for table honey is fair for the time being, and demand from manufacturers has improved. We quote 11@14c for choice comb honey in the jobbing way, and 3@7 for extracted honey, according to quality, on a rival.

Beeswax is in fair demand, and brings 20@23c on arrival for good to choice yellow.

CHAS. F. MUTH & SON,
Apr. 7, 1887. Cincinnati, Ohio.

NEW YORK.—*Honey*.—The demand for comb honey continues fair, and there is no material change in the market.

THURBER, WHYLAND & CO.,
Apr. 11, 1887. New York.

ST. LOUIS.—*Honey*.—We quote you honey still dull. Choice white-clover 1-lb. sections, 10c, and moving slow. Dark 9c, and broken and out of condition, 6@8c. Extracted clover, cans, 5; bbls., 4; Southern, 3@3½. Beeswax, as runs, 21@22; selected, 25.

W. B. WESTCOTT & CO.,
Apr. 11, 1887. 108 and 110 Market St.

DETROIT.—*Honey*.—Best grades of comb honey have advanced since last quotations. Best white-clover in one pound sections 11@12 cts.

M. H. HUNT,
Beeswax, 23c. Bell Branch, Mich.
Apr. 11, 1887.

PHILADELPHIA.—*Honey*.—Honey nominally as last, but no movement whatever, and no demand.

Beeswax is quiet but steady; we quote: Yellow, choice, 22@23; dark, inferior, 20@21; white, 27@28.

PANCOAST & GRIFFITHS,
Apr. 11, 1887. 242 South Front St., Philadelphia.

500 FRAMES OF BROOD

Two-thirds full, well covered with bees (Italian), no queen, in two-frame nucleus hives; just the thing for queen-rearing, \$1 each frame, after June 1st.

Twenty last-years' tested Italian queens, \$2 each. 8-9-10d

M. ISBELL, Norwich, N. Y.

For Sale. Full Colonies of Italian Bees, 2, 3, and 4 Frame Nuclei.

Tested queens before June 1st, \$1.50 each; after, \$1.25 each. Untested, before June 15th, \$1.00 each. After that date, single queen, 75 cts.; six for \$4; twelve for \$7.75. Pounds of bees, same price as untested queen.

I. R. COOD, Nappanee, Ind.

SOLID RED DRONES!

Yes, my American-Albino-Italian, selected queens produce them: **DOOLITTLE** says, "The Reddest I ever saw." I CHALLENGE the world on **BEES**. Send for prices. A PRACTICAL QUESTION.

HOW FAR APART SHOULD APIARIES BE LOCATED, SO THAT THE BEES OF ONE LOCALITY MAY NOT INTERFERE WITH THOSE OF ANOTHER?

IF you have only from 10 to 50 colonies of bees you wouldn't give a blue button to know how far bees will work profitably, nor how many can be kept in one apiary for greatest profit.

As you approach the number 100 or more, you will most likely become intensely interested in both these points. I want to say distinctly, in advance, that I have very little knowledge in this direction that is either exact or certain. I don't know how many colonies can be kept most profitably in one apiary, and I don't know any one who does know. It's a sort of "Will o' the wisp" affair, ever eluding your grasp. But it is a subject that *must* be thought about; for although we may not know the limit, we know most surely that there is a limit beyond which every colony added will decrease the total surplus. I would give much to know that limit. Of course, it varies in different places; and when you come to decide for your locality, you can do it only by comparing your crops of different years and then doing some guessing. If, one year, from 100 colonies you got a total crop of 5000 lbs., and another year, equally good, from 130 colonies in the same apiary you get a crop of *more* than 5000 lbs., it is pretty good evidence that more than 100 colonies can be profitably kept in that apiary. But how can you know that the two years were equally good? Ay, there's the rub. It must be largely guessing. Well, suppose you have used your best judgment, and decide that 125 colo-

nies is your limit for greatest profit, and suppose that you have, altogether, 175 colonies, shall you take half to an out apiary or keep your limit of 125 at home, and take away 50? I think I would compromise, and take away perhaps 75; but it is hardly a matter of great consequence.

Now you must decide how far they should be taken. Even if we had exact knowledge about this, there will always be local reasons that will prevent us from following a fixed rule, because there may be a inden grove in a certain range, or some house where we should like to locate, which is a half-mile or so further or nearer than we would otherwise locate. But it may be of some use to talk about the general rule. For the present let us suppose that 3 miles is the distance which bees work from their home. How much interference will there be if a second apiary is planted within 3 miles of the home apiary? If we represent the range of each apiary by a square field measuring 3 miles each way from the apiary, or 6 miles across, the interference will be shown in Fig. 1.

Fig. 1.

that 50 per cent of A's field is also occupied by B; and according to the figure, if we want no interference the two apiaries must be located 6 miles apart.

The square figure does not, however, properly represent the area of bees' flight. As they fly only three miles in any direction, no bee will ever reach

In this case the shaded part in the middle shows the part of the field that is doubled, or occupied by the apiary located at B as well as by the apiary located at A. It is easily seen,

the corners of the square, and the area of flight will be a circle.

Fig. 2 shows the interference to be less with circular than with square fields. If I have made no mistake in figuring, the shaded part in Fig. 2 is 39 per cent of A's field. But is there not still an error? We have thus far considered that the bees occupy a circular field sharply defined by its circumference, the bees spread evenly over this whole surface, being just as plentiful near the circumference as near the center. But do not the bees become more and more scattered as we approach the circumference, so that the further we go from an apiary the fewer bees we shall find? I know that bees seem instinctively to prefer to fly some little distance when going in search of nectar; or, at least, I think I have seen it so stated; but is this not true only to a limited extent? and is not the general rule that, when you go to their utmost limit of flight, you will find the bees very scattering? Another thing is, that the time and strength involved in making these distant flights counts for something, so that, even if the bees were evenly distributed over the field, an acre taken from near the circumference would count for less in the surplus crop than an acre taken nearer the center. I think, however, we are safe in saying both that the bees are more scattering as we approach the circumference, and also that their labors are of less value than when working nearer the center. This, of course, is merely a general statement, and on the supposition that the field is homogeneous throughout, as if it were one unvarying field of clover from center to circumference. Of course, in actual practice there is no such uniformity, for there may be a fine yield from basswoods near the outside, and nothing yielding near the center. But taking the general view, the field may be considered, not as a distinctly defined circle, equally valuable in all its parts, but as a circular field densely occupied near the center, and gradually fading away to nothing as the distance from the center becomes greater and greater.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 3 represents the idea. With this view of the case, it will be seen that the interference is much less when the apiary B is placed three miles from the apiary A, as at Fig. 4, than we have previously considered. Just what the precise amount of interference is, I can not give in exact figures.

Now, some good friend will likely haul me over the coals for dealing so much in speculation, and ask me why I don't deal in facts. My good friend, the subject is such a slippery one that it is a very hard matter to get hold of any thing very positive. But the subject is one we *must* think about, and we *must* come to some kind of a conclusion when we come to establish an out apiary; and I will gladly

yield the floor to you if you will give us positive information.

So much for theory. As to my actual experience in the matter, I confess it has been such that my views have undergone considerable change. My Wilson apiary is just about three miles from home, in a bee-line. I thought this was too near, but it was convenient and desirable on several accounts. Without knowing any thing about it myself, I took the testimony of others that three miles is about a fair distance for bees to fly, and so they should be six miles apart, to avoid all interference. Making allowance for their scattering flight at the outside, I decided that there would be hardly enough lost by putting them a mile nearer to pay for traveling the extra mile in going back and forth to the out apiary; so I settled upon five miles as about the most desirable distance. But, as I said, the Wilson apiary was distant three miles; and after several years' experience I now seriously doubt if any thing would be gained by placing it further away. At different times, and many times, I have taken colonies from one apiary to the other, and in no case have I ever known the bees to fly back to their old locality. Now, if any of them, in their flight, got back upon their old field, would they not, from sheer force of habit, finding themselves on familiar ground, fly back to their old homes? The shaking-up of the journey, and also the strange appearance of the locality, would make them mark the new location, I know; but still I think the old habit would take them to the old home if they were on the old ground. On the other hand, when sweet clover was in bloom, bees were found on it along the road throughout the whole of the middle mile between the two apiaries, and they would hardly happen to meet just at the middle point between the two apiaries and not overlap. However, these middle bees may have been from some other apiary. I merely give it as my present guess, that three miles is far enough apart for my apiaries, and make no promise to adhere to that opinion for any specified length of time. Have others any experience that will help toward a guess in the matter?

At different times I have asked questions of others, and, without exception, received answers something after the following fashion:

"Suppose an out apiary is established at a proper distance north of the home apiary, in what direction would you plant a third apiary?"

"South."

"Where would you plant a fourth apiary?"

"East or west."

"Well, suppose we say east, then where would you plant a fifth?"

"West."

"And a sixth?"

"Well, somewhere further out."

In every case the idea was that a circle, or row of four apiaries, would be planted about the home apiary, something like Fig. 5.

Fig. 5.

Fig. 6.

This is well enough if only five apiaries are to be

established. But if the number is to reach seven or more, it is just as well to put six as four in the first circle, as in Fig. 6.

C. C. MILLER.

Marengo, Ill., April, 1887.

Many thanks, doctor, for telling us just what we have got to meet, sooner or later. Now, I happen to know that a good many localities are more or less overstocked, perhaps not often by one single owner; but many times where a whole neighborhood goes to bee-keeping, the result, unless during extra seasons, is a small amount of surplus per colony.—The distance bees fly has been a good deal discussed during years past; but I feel pretty well satisfied that you are right in deciding that bees seldom fly more than three miles; and notwithstanding all the facts that have been brought forth, I do not believe they work profitably more than half that distance. I feel so sure I am right that I have furnished buckwheat and alsike clover-seed to our farming friends who are no more than a mile and a half distant from our apiary. Where they live two miles distant, we sometimes let them have it at half price. When we first brought our Italians to Medina we rarely found them more than two miles from home. When there was a scarcity of blossoms, however, they were occasionally found two miles and a half away. This scarcity always occurred between fruit-blossoms and clover. At this time, the wild thorn-apple would be covered with Italians two miles from home, while the same trees three or four miles from our apiary were covered with black bees and no Italians. Perhaps there were not Italians *enough* at that time in our apiary. These observations were of no avail a year or two later, because the Italians had got into the woods. I think you are right about it, and Fig. 6 would be the plan I would suggest for seven apiaries. You may remember, the same thing is suggested in our A B C book.

ABOUT DRINKING-WATER.

FRIEND TERRY DISCUSSES THIS IMPORTANT MATTER.

THE writer traveled some during the past winter with Prof. Detmers, of the Ohio State University. Noticing that he did not drink any water, but always tea and coffee only, I asked him if he was afraid to drink water when away from home. "Yes," he replied, "for there is as much sickness and death caused by drinking impure water as by drinking liquor. I drink no water when away from home unless it has been boiled. Then it is safe." Not long afterward I met another scientific authority, and told him what Prof. Detmers had said, and asked if that was correct. He laughed, and said Detmers had put the case a little too strongly against water; but still there was a good deal of truth in his statement, for very much sickness and death is certainly the result of drinking impure water. Not long after, I had the pleasure of eating supper with Dr. C. L. Mees, of the Athens University, at a hotel in the city. I kept watch, knowing that he was a thoroughly posted man, to see whether he would drink any water. He drank some. Then I asked him if he wasn't afraid of it. He said there was some

risk, perhaps; but he would take the chances as long as he knew there were no cases of typhoid fever or similar diseases in the city. He was more afraid of some disease that was present being communicated through the drinking-water, than of disease that originated from the impure drink. He seemed to think that these diseases were not started by impure water or foul air, but that they lowered the tone of the system so that the germs of typhoid fever, etc., if they happened around, were far more likely to find lodgment and a proper place to develop in.

Well, I told the doctor how much pains we had taken to have pure water at our house, so as to get his advice. I told him we had a slate roof on the house, and a cement cistern, with a brick partition in it to filter the water. He said: "If you clean out your cistern once in a year or so, you have got as pure drinking-water as you can obtain. If you had a shingle roof, why, then you ought to let the first rain that falls in a shower run off; and after the roof becomes clean, turn it into the cistern. If you burned soft coal, this would be best, even with your slate roof; but with anthracite coal it will not matter much." (This brick filter is simply a partition built up in the cistern, so as to have about one-fourth of the space on one side, and three-fourths on the other. The water flows into the larger space, and is pumped out of the other. We used quite hard bricks and cement. Our water has always been perfectly clear.)

Next, I told of my well, where we get nice cool drinking-water in summer. In the winter we use only cistern-water. The well is in the dooryard, a few feet from the kitchen-porch. The yard and the fields around are kept clean and pure; that is, no slops are emptied more than once in a place, and the privy-tub is water-tight, and the contents absorbed with dry muck. I spoke rather boastfully, as I have taken a good deal of pains in that line, of my nice pure well-water. The shrewd professor smiled quietly, and remarked: "You can not say that your water is pure, although you have taken wise precautions, such as every person should, to try to have it so. You manure your fields, and more or less vegetable matter decays on them. The rains fall on these fields, and the water goes down and carries with it some impurities from this decaying vegetable matter. The earth will not filter them all out. In fact, it is next to impossible to filter them all out. They will go through the brick wall in your cistern with the water. Careful experiments have shown that typhoid germs can not be filtered out of water by earth. Your water may be bright and clear, but it may not be entirely pure. In fact, chemistry hardly dares to say, after analyzing, that a given sample of water is harmless. It is far easier to tell those which are certainly harmful. You have taken every precaution that you can in your location, but do not be too positive about your water being too pure."

Well, I was taken down, I assure you, friend Root. Perfection can not be attained, perhaps, in this direction nor any other; but we can certainly all work toward it. However, they say boiling would render the water *perfectly* safe. Certainly every one ought to take all the precautions we have. One should do all he can for his own protection, according to our best present light, and then trust in Providence.

A man told me this last winter, after hearing me

talk at an institute on the subject, that his slop-drain from the house ran by the well, and within ten feet, and that it was built of common drain-tile, and asked if I thought there was any danger in drinking the water from the well, under the circumstances. The slops could run out between every joint in the tiles, and it is only a matter of time when that water will be dangerous to drink. I told him so. If he does not tend to it immediately, I have no faith to believe that Providence will save him. Let us all look to our water supply, and see if we have fairly earned the right to trust in Providence, with an entirely clear conscience.

One more point in the same line. It has been clearly shown of late, that germs of disease can be carried in ice, and thus get into our drinking-water. To illustrate: Some children died of diphtheria, as it was called. Several physicians were employed to hunt up the cause. They could find nothing about the house or water or surroundings to cause the disease. They were about to give up when one suggested they examine the ice. In it they found the germs of swine plague. They soon found out that some hogs that died of the disease were thrown into the stream from which the ice was cut. This was done just before it froze up. In many other cases, disease has been traced directly to impure ice. So one must look out for the ice, now, as much as for the water.

T. B. TERRY.

Hudson, O., April, 1887.

Very good, old friend; but it seems to me you are in a hurry to drop your subject this time. Your last point, about disease being contained in the ice, is certainly a most serious one, and I felt almost vexed to have you drop it with so few words. I have for years been very sensitive in regard to drinking-water; that is, I do not feel right after drinking certain kinds of water, when I do feel right by getting water that Nature seems to say is all right. Not a great many years ago I felt thirsty all the time, but none of the water from any of our wells or cisterns seemed to satisfy my thirst; that is, if I drank as much as I felt like drinking it made me feel worse than if I had not drank at all. I drank milk for a good many days, but Nature seemed to say, "We have had plenty of this stuff; we want some good pure water." One evening as I was going over the factory after the hands had all gone home, I heard the rain upon the roof, and something seemed to say, "There, that is exactly what I want and have been wanting." I replied, or perhaps reasoned within myself, that the water from our slate roof over at the house must be just as good, but it tasted, at least faintly, of the lime used in making the cistern, and nature seemed to call so strongly for the pure water just coming from the clouds that I got a great big tin dish-pan and set it outdoors until there was enough for a drink. It seemed to fill the bill exactly. In fact, it was so delicious that I drank more and more. I decided to test the matter thoroughly by drinking an enormous quantity. To my astonishment, no unpleasant results followed. I went to bed and slept soundly. From that day to this I have been in the habit of catching water from the clouds, or melting snow when we have snow, instead of rain, and I really believe I can drink a quart of water distilled from

Nature's laboratory, and grow fat on it—that is, if anybody *can* grow fat on pure rain water alone. Soft water from sandstone springs seems to answer the purpose in the same way. I can drink and drink, and it does not seem to make any difference how much I drink, by waiting so as to have an interval between these drinks. Pure soft water seems to act on my system as it does on my face and hands—it washes away the accumulations and debris, as it were. Hard water from most of the wells, especially from the wells in clay soils, does not answer for me. Nature submits to it for a while, but pretty soon she says, "We have had all of these salts of lime and earthy matter we can dispose of for some time to come; now give us some pure clean water that does not leave any residue when you boil it down."

Of course, I have no right to insist that soft water, or the fresh water from the clouds, is best for every one; and I am not sure it is *always* best for me. Sometimes when I taste the water from mineral springs, or springs that contain a considerable quantity of mineral salts, Nature seems to say, "This is a good thing; let us have quite a little of it." But sooner or later the demand comes, clearly and unmistakably, for the soft water from the clouds. Tea and coffee cease to fill the bill. Even lemonade is not the thing, and back I get again to my favorite beverage of rain water caught in a tin pan.* At one time, one of the conductors that brings the water from the slate roof to the cistern became leaky, and I caught a dipperful right where it passed into the cistern, but before it had got there. This seemed to fill the bill about as well as rain water out of the tin pan; but I imagined that even the slate roof and the tin pipes had given it a slight taint. Suppose, friends, you think of this matter, and experiment for yourselves. I do believe that a natural, unpurverted taste is a safer and surer guide than any rules that can be laid down, even by "big doctors." One who feels perfectly stout and well will not, perhaps, need to be so "notional," as some may term it; and I quite agree with the doctor who said that the danger from impure drinking-water is principally to those whose systems are in a weak condition, and ready to let fevers, etc., find a lodgment. I believe, however, we may keep our systems in a high and healthy tone by being careful about our food and drink.

I once used considerable ice (putting it directly into a tank used for drinking-water) that I became satisfied was affecting me injuriously. Investigation showed that it had been cut from a pond where cattle drank in the summer time, and where they could stand in the water up to their knees. I know the symptoms of bad water on myself so well, that I think I can tell it almost at once. When I was a boy in my teens there seemed to be a sort of ague and fever hanging around me. I studied over the matter until I felt satisfied that the feelings origi-

*I have often kept rain water, thus caught from the clouds, in an unglazed covered stone jar, placed in the cellar. The unglazed jar keeps the water moderately cool by evaporation, and even in the hottest weather in summer I find it very palatable and refreshing.

nated from the water we drank. We were in a new country, and no wells had been dug. Where I was boarding, the water they used and drank came from a hole dug in a low spot in the woods. They called it a "spring," but it was so full of organic matter that a very cheap microscope showed the wigglers by the thousands. I changed my boarding-place, and commenced drinking water from a deep well that showed none of this animal life, and I was myself again; almost at once.

By the way, it may not be amiss to state that it is a popular fallacy to suppose that there are live animals in our best drinking-water. It is not so. The water from a good well or spring is almost if not entirely free from any such forms of living animals. I have often wished we could have a cistern made of glass. A great big glass bottle would suit me. Then, of course, we should want a good filter to prevent dust, leaves, and trash of any kind from getting into our glass-bottle cistern. I do not like cement cisterns, for the reasons I have given; but perhaps when the taste of lime has all been washed away they may do very well. Wood is used entirely in some places; and if kept well cleaned out, it may do quite well—I mean for constructing cisterns. Iron or wooden pipes for the water to *pass through* are perhaps unobjectionable, but I have never given them the test mentioned above.

VARIOUS TOPICS.

DARK HONEY FOR THE COMBS.

YOU ask to hear from readers who have found it best to have extracted honey light, and to get the dark honey in combs. That is my experience. Some people were prejudiced against extracted honey, because they supposed it would necessarily be dark and strong. The majority of customers prefer light honey to dark, and comb to extracted.

My bees were not inclined to help me in this matter, however. They work more readily in frames at any time, but especially during buckwheat bloom, some refusing to enter sections, and others doing but little, although I contracted the surplus apartments, and tugged them up warm. The grocer to whom I sell asked, "Why don't you have more of the dark honey in the comb?" He also tells me that yellow wax brings a higher price than the light. Why is it so? The light is made from cappings, the dark from old combs. He sometimes melts over the light wax, adding butter-color.

KING-BIRDS, AND WHY QUEENS DISAPPEAR.

In answer to one who asked why his queens disappeared just when they should commence laying, I would say they were probably killed while flying out. I had a similar experience, the trouble ending when a king-bird was shot. Prof. Cook asks whether the king-bird receives stings. I think not. I watched this one for some time. He would catch a bee, alight on an old apple-tree, thump the bee against a limb, and then swallow it. I watched him catch and eat thirteen.

SALT FOR BEES.

Bees want salt, but not a large quantity—about a tablespoonful to a pail of water. When I make a

strong brine they prefer fresh water; otherwise they work on the salt water early and late, and work right on, during rainy days as well as sunny ones.

ALSIKE.

Will you please tell us how to manage alsike clover to have it come into bloom just as white clover begins to fail? Should it be pastured or cut early, and how would that affect the hay and seed crop?

RASPBERRIES.

So many are praising the Cuthbert raspberry that I wish to say that we think the Philadelphia more profitable, both for honey and fruit. It is true, the plant is a trifle less hardy, the berries are not as good a flavor (some think them better), and they are not quite as large or hard; but they fill both berry and honey boxes. The Cuthbert is good for a late fancy berry.

I am glad to see the recipes for cakes and candies. Writers should mention the kind of honey used. Buckwheat honey makes a richer cake than white-clover honey. The strong taste and stronger smell do not recommend it to the fastidious ones, however. What can be done to destroy that and the sharp twang in some of the light honeys? A trace of propolis sometimes causes a smart taste.

Delavan, Wis.

6—L. WILLIAMS, 13—13.

Thanks, friend W., for your hint in regard to the amount of salt to be used in a pailful of water. I think now that I can remember failing to get bees to use salt water, just because I made it too strong.—Alsike clover can be kept from blooming either by mowing or by pasturing. I can not tell what the effect is on the hay or seed. Perhaps our readers who are accustomed to cutting it early can answer.—I do not know how it is possible to remove the sharp twang you mention, noticed in some kinds of honey.

SPREADING BROOD.

A FEW HINTS FOR BEGINNERS AND OTHERS.

AS spring is drawing near, a few words on the above subject may save some beginner in bee culture much loss by the untimely spreading of brood in early spring. For a number of years I have been in the habit of spreading the brood in spring, and I am satisfied now that I have gained little if any thing by so doing; and as I struck on a plan last spring that suits me much better, and is perfectly safe, I wish to give it. As soon in the spring as the bees begin to gather pollen they are confined to the number of frames containing brood by a division-board, or a frame solid full of honey. When these are full of brood, the division-board or frame of honey is pushed back, and an empty comb placed beside the brood-nest. If the colony is in a prosperous condition, the queen will take possession of this empty comb just as quick as she would if it were placed in the center of the brood-nest. The above plan is the one we used last spring, and I never had bees build up so fast and become strong as early in the spring as they did last year.

I believe it is a bad plan to break the brood-nest in the spring, as it is a shock to the bees that they do not get over in a number of days; but when the combs are placed at the side, the brood-nest is enlarged without disturbing it.

G. A. WRIGHT.

Glenwood, Susq. Co., Pa., Feb. 1, 1887.

OUR WOOD-WORKING DEPARTMENT.

A GLIMPSE AT BEE-HIVE MACHINERY.

AS announced in a previous issue, we herewith give our readers a view through the central portion of our wood-working department where all our hives, sections, frames, and every article made of wood, pertaining to apiculture, is manufactured. The room which you see is 44 x 96 feet, and there is scarcely a belt to be seen; and where one does come up into the room it is boxed so that there may be no danger to the workmen or small boys engaged in picking up sticks. All the shafting and pulleys are in the basement below; and nobody but experienced men go down to oil, or, to put on and take off the

the room, you will notice a large pipe. Along the latter, at different intervals, are openings through which the hot air is allowed to escape. The large pipe from which this hot air comes, communicates with a smaller exhaust-fan. This is connected with a coil of steam-pipes, aggregating 600 feet in length. The iron casing inclosing said steam-pipes has a duct communicating directly outdoors. The revolution of the fan causes a current of air to blow into the open-air duct, through the coil of hot steam-pipes, thence through the fan, and finally into the large tin distributing-pipe which we have already described.

In spite of all precautions we have made for the protection of our men, we have had a number of serious accidents. Somebody,

A VIEW IN ONE OF THE ROOMS OF OUR NEW BUILDING.

belts. Although there are a great many saws running, contrary to what you might expect there is little if any inconvenience from sawdust flying in the room.

We have previously stated, that a 52-inch exhaust-fan is located in the basement. Connecting directly with this is a 14-inch galvanized-iron pipe, and this pipe communicates with every wood-working machine by means of a smaller pipe. Thus the sawdust and shavings, as fast as made, are carried directly into the boiler-furnace. The men you see there at work have things not only arranged as safe as possible, but all small particles of dust are removed from the atmosphere of the room by the apparatus we have described. In addition to this, in cold weather, pure hot air is blown into the room.

Near the ceiling, in the central part of

perhaps, has grown a little careless, and the whizzing saw becomes less and less dangerous to him until he has allowed his finger to get too close to the saw. The result is the loss or mutilation of one or more fingers. Perchance he tries a new experiment by letting a block down over the saw. Before he knows it the saw has snatched it from under his hand; and then, quicker than a flash, his fingers are drawn against its teeth. Sometimes a stick tumbles on to a saw, the speed of which shoots the stick like a bullet. If no fellow-workman stands in its range, all well and good. We mention these facts to show you how accidents may happen, and that all of you who have to do with saws may be careful.

Having given you a general description of the way in which our wood-working department is constructed, let us now proceed to

some of the details. The machine in front of the young man holding a pile of sections, is what is called a Gray one-piece section-machine. He is in the act of putting a pile of sections into the machine. Having done this he steps around to the other side; and as fast as the finished sections drop down on a tray with a zip, zip, zip, he piles them into a box holding 500. This machine is automatic, and one man can feed the strips of sections, and box them up, while the machine is in motion. You will notice at the right of the young man, four stakes sticking up. Although the engraving does not show it, this is really a truck which can be pushed about the room, filled with hives, sections, or whatever else the men may be working on. We have about two dozen of these trucks constantly in use, not only in our wood-working room, but in all our departments.

At the rear of the young man are several sawyers ripping section-bolts into strips 18 inches long, and $1\frac{1}{2}$ inches wide and $\frac{1}{4}$ inch thick. As they leave the saws, these strips, or one-piece-section blanks, are perfectly smooth on both sides. They are picked up by small boys, and put into the trucks to which we have already referred. These trucks are then shoved up to the section-machines, only one of which is shown in the picture, the other being located in front of the one which you see. Near the center of the room is a couple of cross-cut saws, where all the cross-cut work is done. Further back is the planer. At the right is a band re-saw. This machine is so large that it reaches to the ceiling, though in the engraving it is represented as much smaller. Perhaps right here a little description of this saw may be interesting to some of our readers.

A heavy iron casting holds two wheels in such a way that one wheel is directly above the other, and the distance apart varies from 6 to 20 inches, depending upon the width of the stuff to be ripped. These two wheels are connected by a steel belt, one edge of which is serrated, or toothed. As the wheels revolve at a high rate of speed, this steel band, of necessity, travels at the same rate. The superiority of the band-saw over the ordinary re-saws rests in the fact that it will cut thinner boards with far less waste, and will do it more rapidly. It also cuts to the best possible advantage; that is, it is always cutting perpendicularly against the stuff. A couple of instances will illustrate the foregoing statements. Before we proceed, however, we will say that "re-sawing" means ripping thick boards into thinner ones. Well, let us take an inch board and run it through an ordinary circular re-saw, cutting it into as many thin boards as we can. The best circular saw for re-sawing a 20-inch board makes a waste of not less than $\frac{3}{8}$ of an inch. On cutting, we shall have only two boards left, each a small trifle over $\frac{1}{2}$ inch thick. It will now be impossible to re-saw these again, as a large circular saw would tear them all to pieces. We will next take an inch board and see how many thin boards we can cut out of it with a band re-saw. With the latter there is a waste

of only $\frac{1}{8}$ of an inch; and after once cutting, we have now two boards nearly half an inch thick. We adjust the rollers and put one of these again into the band saw, and find we are still able to re-saw it up into three boards. We can thus re-saw an inch board up into six thinner boards. Our Mr. Warner hopes to be able to cut wood-separators with it. As yet, however, the work is a little rough as it leaves the saw; but by filing and setting the teeth in a certain way, he may succeed in doing so.

In all kinds of work requiring thin boards, this machine will save us, in the course of the season, a considerable amount of lumber, which otherwise would go into sawdust. It was purchased of Fay & Co., Cincinnati, O. The cost was nearly \$400, and its weight two tons.

Let us now pass on. At our left, as we go up, is one of the cross-cut saws to which we have referred, near which stands our Mr. Warner, the foreman. He it is who stands in the distance (just over the young man's right shoulder in the foreground). Our engravers hardly did him justice; but as he is supposed to be quite a long way off, it will answer tolerably well. Just in front of Mr. Warner is the machine for cutting out insets in the section-bolts. This machine we illustrated and described in GLEANINGS, page 154. The next machine is for grooving the ends of the one-piece and four-piece sections. Still further on is a saw-table for ripping up our $\frac{1}{2}$ -inch lumber into all-wood frames. Every time a board passes over the gang-saws it rips three bottom-bars, top-bars, or end-bars, as the case may be. Last of all is an automatic machine which takes a pile of top-bars, grooves them for a comb-guide, and throws them down into a basket, without any one touching it, except a small boy who now and then gives it a feed of top-bars.

It is in this department where we turn out daily 20,000 sections; and we can and do make a thousand hives a day, besides doing other work.

About a car-load of lumber is cut up every three days. As fast as the pieces are finished they are piled up in the trucks and pushed into the main building. Sometimes a truck-load of stuff is put on to the elevator and carried into the second story, where the hives, etc., are put together.

In closing we would say that our artist took a view of the saw-room one afternoon in the dull season. If you will imagine more men, more machines, more piles of stuff, and, in general, more business, you will get a fair idea of the way things look in there during the rush which is just now coming upon us. Yes, the rush is just beginning. The foreman of our packing department tells us we are shipping about a carload of goods by freight every day, to say nothing of the mail and express.

Later, April 12.—We are pained to give the sad intelligence to our readers that one of our head sawyers, a man well on in years, had his hand mutilated so badly this morning that it had to be amputated. For some reason which no one can explain, he put his hand under the cutter-knives to one of the

section-machines seen in the foreground. He was trying to disengage a section-blank, which was caught. Instead of taking an iron hook which is provided for the purpose, he used his hand. We give you this fact, in order to impress upon the minds of you who have to do with saws or hive-making machinery, to be careful; be afraid of the saws; remember the terrible consequences.

OUR P. BENSON LETTER.

Luv & Beafstake & Beestings.

A ROMANTS.

INTO the life of evry I cum a time which taken at the flud leads on to forchune. Sith a time hed cum into the life of Emmy Jane. That was her 1st name. Emmy Jane Cary was her fool name. She was a hansum creetur, fare as the dooy breth of a mornin zeffer in the witching cam of twilite revery. Her parents on her father's side was a farmer, with four (4) sons and three (3) dotters. Emmy Jane was 1 of the dotters. Willy Davis hed been keepin compenny with her, but for sum time now a cool strain of feelin hed groad up atwixt them. I no oll about the koz of it but I druther not tell. Willy told me in confidents. Suffize it to say that the gap kep gittin wider an wider. You no sitch things are ap to go that way. He was hotty & she was proud, & nether wood give in a inch.

EMMA JANE AND POOR WILLY.

But the epock into her life to whitch I refurred in the beginnin was about to arrive. Willy hed bin up to Jack Wilsen's to git a settin of eggs from Jack's muther, not that Wilsen's hed enny better breed of hens, but they are ap to do better if you change eggs. Nowadaze people makes a fuss about thorowbred fowls & all that sort of thing, but bless you, thay was jist as good chicken pie years ago when thay diddent no enny thing about breeds oanly to change eggs now and then. But Ime gettin off the subjeck. Curuss how a buddy will run from 1 thing to another. Now thares Dan Jones. Heal commens to tell sumthing and run off on to sumthing else & like enuff forgit all about what he started on. Its reel tryin to lissen to sitch fokes. So as Willy was goin by Emmy Jane's he kep his hed down jist as if he diddent care a speck for her. That was the way with both of them, coald & indiffernt outside but all the time hed a give his oald boots to make up, & she wurshipt the verry ground he trod on. But jist then he heer a offul screech, and lookin round he see it was Emmy Jane. The bees was after her and she was a gittin lively, a yelpin evry step. Willy was afearod of bees but he summond oll his #twood and went to sucker her from the impending dainger. He 1st poot the eggs carefool like

in the fents corner. Eggs doant hatch near so good if thare shook up mutch, but it doant hurt them nun for cookin. Emmy Jane hed throad her apen over her hed, so the bees coddent git at her, and when Willy cum up a strikin wildy with both hands them bees jist piled onto him, & give it to him in both ize. You dot to a seen him. Thay was mourn 20 stings, and in lessen 2 minites boath ize was jest about shut. That fetcht Emmy Jane. She sez to him, sez she, "O my poor Willy," sez she, "are you killed?" "Not quite," sez he. "O," sez she "and you risked yure life to save me." And then she got him in the house and pored camfire & salleratus in his ize, & tied rough beef on them & he toled her thay never hed bin a thing atwixt him & Dell Stull, that he hed jist gone thare to git a yellow rose bush and wuzzt waitin on Dell at oll, but when Emmy Jane got mad he was too proud to explane.

Menny yeers has past, and Mrs. Davis, she that was Emmy Jane Cary, helps take care of the aperry & Willy refers with joy to the time when the bees got him back Emmy Jane.

P. BENSON, A. B. S.

THE CHAFF HIVE VS. SIMPLICITY.

AN A B C'S EXPERIENCE.

I SHOULD like to know why my bees are breeding so much faster in the Simplicity hives than they are in the chaff hives. I looked at my bees on the 20th, and found in a Simplicity hive a good-sized patch of brood and young bees already hatched out. They are hybrids. The queen is an Italian dollar queen. I got her from J. W. K. Shaw last spring. The queen must have begun to lay about Jan. 1st, or a little after, when the mercury was about down to zero. We have had a cold winter. Snow fell on the 5th about six inches deep. Some of the other colonies are in chaff hives, and they began breeding only a few days ago. They are strong swarms, on six L. frames, with plenty of stores, and well packed with chaff, according to your directions in the A B C book. The bees in those chaff hives are hybrids, and of the same lot of queens as the one in the Simplicity hive.

I do not find that the chaff hive has many advantages over the S. hive. I have blacks and full-blood Italians in one-story Simplicity hives, with chaff packed on each side, and a thin cloth over the frames. A little chaff is spread over the cloth, and a Simplicity cover put on. They are in fine condition now. Some have sealed brood; some have 4 frames and others only 3; and I expect them to come through good strong colonies in the spring.

We have certainly had a hard winter. I think the most of the bees here in box hives have died. Some absconded last summer; some were killed in the fall, and a good many have frozen this winter.

I like friend Doolittle's method of introducing queen-cells. I had my queens purely mated, rearing them late in the season, by keeping Italian drones in a queenless colony.

I like GLEANINGS so well that I am always anxious for it to arrive. I can not afford to do without it. I have read a good many bee-journals, but GLEANINGS is the best of any that I have read. I like to read your Home talks. It makes me feel like calling you brother in place of friend. Your goods are always the best, and always give satisfaction.

Jubilee, Davidson Co., N. C., Jan. 29, 1887.

BEE-LEGISLATION.

SOMETHING ON DR. C. C. MILLER'S SIDE OF THE QUESTION.

FRIEND ROOT:—I should like to thank Dr. C. C. Miller for the way he has handled the opponents of legislation in the interests of bee-keepers. I believe he has come out ahead in every article he has written on the subject. His statements have been clearly and very concisely made, and I know that no one can truthfully say he has not been honest and candid in every instance; and he has most persistently stuck to the subject, which can not be said of any other one who has written upon the subject in GLEANINGS.

On p. 180, March 1, he says: "Controversy is not at all to my taste, and in the present case I have the uncomfortable feeling that, by advancing my views, I have lowered myself in the esteem of those whose good opinion I highly value." Can it be possible the doctor feels that way? When I read that sentence it gave me a feeling of sadness, and it does yet every time I think of it; for it matters not how much difference of opinion there may be, all who know the doctor will certainly give him credit for being sincere, and probably I should but voice the sentiment of many bee-keepers interested in the subject in saying that perhaps he is as much in advance of us all on the subject as "Old Abe" used to be found in advance of public sentiment in many things during the war, and that the doctor has *not* lowered himself in the esteem of those whose good opinion he so highly values, but that he has rather *raised* himself in the estimation of all. It may be possible that he is on the right track after all, and only time is needed to show such to be the case. When he proposed the appointing of a committee, at the N. A. B. K. Convention at Indianapolis last October, to investigate and report on the desirability and feasibility of legislation in the interest of bee-keepers, there was plenty of opposition; but, if I am not mistaken, not one who opposed the proposition then has said any thing about it in GLEANINGS. When such a man as Dr. Miller starts off from the beaten track, it is enough to make thoughtful people "think twice" before showing opposition.

Before there was any discussion of the matter of legislation, he wrote an article on the subject; and on page 781 of GLEANINGS for October 1, 1886, in the first sentence of the second column he says: "In plain words, I take the radical ground that legislation is needed, whereby, in some way, under proper limitations and restrictions, by paying for it, I may have the control of a number of acres or square miles as a range for my bees." Now, it seems to me that if every one who has written on the subject had kept that statement in mind, it would have prevented the use of such terms as "such a covetous and selfish spirit . . . as to favor legislation that would deprive any one, so disposed, of the pleasure of keeping bees," being applied to the doctor. What is there so very covetous or selfish in his or any one's else paying for a privilege to do a legitimate business in a certain locality? And you, friend Root, in your comments on the doctor's article, say, "Your ideas are good and sound, but I am afraid it will take a good while to get them into shape as they are in agriculture and some other pursuits." Well, what if it does? does that lessen the need or desirability of making the effort? If I am not mistaken, the Home of the Honey-Bees didn't grow up

in a day, but it has taken years of hard thinking, hard work, and push, and thousands of dollars, to grow that fine home and that large and perfectly ordered and well-stocked factory, etc., that have necessitated the building of a railroad depot for your accommodation. Have such bee-keepers as Cook, Dadant, Doolittle, Demaree, Heddon, Hutchinson, Jones, and the scores of equally successful ones become such by a few months of study and experience? Has it not been by the persistent work of years? Thanks, friend Root, for saying that the doctor's ideas are "good and sound."

In another article the doctor asks, "What kind of legislation is needed?" and then very frankly says, "I don't know." If there could be some feasible way devised, by legislation or otherwise, always justly, of course, by which those who desire to make bee-keeping a specialty could control the desired locality, then it might be desirable to make special effort to stock the locality with alsike, alfalfa, Chapman honey-plant, and other honey-plants suitable to the locality. It seems that you, friend Root, very naturally thought of this matter several years ago, when you were putting out your basswood orchard, and very naturally came to the conclusion that you could make it unprofitable for any one to attempt to make honey-gathering from your honey-orchard profitable, for you expected to raise queens and bees for sale, and not surplus honey.

On p. 945 of GLEANINGS for 1886, a writer says that the doctor has baited his hook for "suckers" and caught one at the first cast, etc. Ridicule is not argument, but with many it has more weight. If thinking as the doctor does makes one a "sucker," I should not be surprised if he had caught enough to completely brush off that "uncomfortable feeling" if they would only use their bee-brushes. It seems to me that the *desirability* of controlling a prescribed locality by those making bee-keeping a specialty must be apparent to all. Its *practicability* is another matter. One would hardly think of attempting to raise grain or stock without having first obtained control of the needed locality.

I am afraid that the present generation of bee-keepers would have to live longer than father Abraham did before it would see all bee-keepers actuated by the spirit he was. If they were so actuated, legislation would not be needed. The doctor's articles plainly show that he has in view the interests of those engaged in the same pursuit he is, and fully realizes, as does Mrs. Harrison and all others, that, in order to raise "peas, beets, lettuce, and cabbages," people have "priority of location," and pay for it too; but where has the doctor said any thing about "priority of location," or suggested that any thing be done that would give a privilege to one bee-keeper that might not be enjoyed by any other? W. W. Maltby does some good rhyming on page 66 of GLEANINGS for 1887, but asks Dr. Miller a rather strange question when he says:

Now, Bro. Miller, pray tell, if you can,
Why for God's gifts we pay tribute to man.

It seems to me that Bro. Maltby answered his own question before he asked it when he said:

God made the earth, the earth raises flowers;
We don't produce them, so they are not ours.

Don't we pay tribute to man for the gifts of God because they are gifts to others and not to ourselves? I don't expect to have the benefits of God's gifts to others without paying for them.

Auburndale, O., Mar. 30, 1887.

A. B. MASON.

A NEBRASKA APIARY.

RIPENING HONEY, WINTERING, ETC.

HAND to you a photograph of my chaff-hive apiary. If you could simply glance at the original a moment you would soon decide that the artist has made a truthful picture. It was taken Nov. 30, 1885, soon after the leaves had fallen, and the bees had been prepared for winter quarters. It then comprised an apiary of 100 colonies, 72 of them being packed in our summer and winter chaff hive, which we will briefly describe further on, and as shown in the cut. The apiary is situated on a slight elevation, gradually descending to the east. If the observer will take the pains to turn himself about, facing the west, holding the

of the room warm, and of a degree necessary to cause the honey to be thick and of a well-ripened state for the market. Again, we find that honey put in shallow vessels in this kind of a place will ripen with nearly the same rapidity that it is ripened in the hives. During the winter months this upper half-story comes quite handy for storing away, until another season, all surplus honey, cases, and all other apiarian supplies that may be made during the season of rest for the apiarist. The lower part of this building is used for the manufacture of all our bee-hive work.

After several years' experience in wintering bees we have learned that bees, if wintered on their summer stands successfully, must have protection against the extreme temperatures of our

APIARY OF J. M. YOUNG, ROCK BLUFFS, NEBRASKA.

picture before him, he will get a correct idea of which is north, south, east, or west. The cut includes nearly all the apiary, with the exception of a few hives left out at the left-hand corner.

The building, as seen in the background, is the work-shop and honey-house combined. It is in size 12 x 18 ft., and a story and a half high, although it looks from the engraving to be considerably smaller than it really is. The upper half-story is used for nearly all purposes, but more particularly for storing comb and extracted honey during the summer and fall months. From several years' experience in raising honey we have come to the conclusion that this is just such a place as is needed for ripening comb and extracted honey, from the fact that the sun's rays strike the roof of the building almost directly, always keeping that part

cold winters. With this object in view we have constructed our summer and winter chaff hive as shown in the cut. Since its introduction we have wintered with no particular loss. In fact, wherever it has been used by other bee-keepers it has given good satisfaction.

In preparing the bees for winter we remove all surplus frames from the upper story, fill in with dry leaves, or, what is considered best in this locality, dry oats chaff packed down very closely with the hand. If they are supplied with plenty of good honey they will not need any further protection or attention, from the time honey ceases in the fall until it comes again the next season.

The small hives, as seen in the foreground, are queen-rearing hives. They are made to hold three frames of the regular Simplicity size. Nearly all

our queens are fertilized in these hives, and they are quite handy for various other purposes, such as shipping, etc. The small holes, as shown in the ends of the hives, are for ventilation, and are put in when the hives are made. On the cover of these small hives are handles to catch on by, and are just as handy as a common gripsack to carry around. When the queen-rearing season is over they are all gathered up and placed away in the dry until another season.

By observing closely there may be seen some square-looking hives near the center of the engraving. They contain two sets of combs. They are used for extracting purposes. The frames are of the Gallup pattern. These hives we use solely for extracting, taking the honey from the upper story only.

The trees, as shown in the engraving, are fruit-trees, some of them being quite large. During the summer months we like plenty of shade; but during winter we want no shade.

Later.—Since writing the above the bees have had a good fly, and they seem to welcome the warm genial sunshine. On examination at this date, March 7, we find that there are 10 colonies out of 96 that have failed to answer to roll-call. Three of those that are dead were in our chaff hives. This is about the greatest loss we have ever had in this hive. Two of these were very late swarms, therefore we could hardly expect them to stand such a trying winter as the present one has been.

As it is just about like you, friend Root, to want to know about everybody, I will say, in conclusion, that I have been a subscriber to GLEANINGS nearly ever since its existence, and to it I am indebted for a large share of instructions in connection with my experience in bee culture. That part called *Our Homes* I have always taken a special interest in, from the fact that its teachings coincide with my views and daily routine of life. I don't use tobacco in any form whatever, and am a strong worker against intemperance. I am an unmarried man, not very old, and if you want to see a fellow who looks like me, just take another peep at the personage in the engraving, who holds a Clark smoker in his hand, and is holding on to a small apple-tree.

Rock Bluffs, Neb.

J. M. YOUNG.

I am sure, friend Y., we are very glad to get a glimpse of yourself and the place where you find "something to do, and how to be happy in doing it." But why don't you tell us something about the rest of the folks? Is the calm-looking chap back of you your brother or cousin? And how about the man with the dog? Is that a pipe he has in his fingers? If so, why don't you labor with him gently? And then, again, there is that nice-looking woman near by, and the little chick that seems either afraid of the bees or of the photographer. May be she thinks the machine upon stilts is going to "shoot" pretty soon. May be the woman is your sister or cousin—possibly somebody's else sister. But I suppose courtesy forbids our being inquisitive any further in this line. I know you say in your letter that the photograph was taken when the leaves were off the trees; but it is so much more expensive to engrave dry brush than green foliage, that I told the artist he might put some foliage on the trees, so it would look more shady like. Is the fellow who is leaning

against the ladder in the background the man who does all the work—that is, with the assistance of the fellow who is making the dog stand still? The two are in their shirtsleeves, while the rest of you seem to have your Sunday clothes on. Never mind, friend Y.; we are satisfied that you are well fixed, in any event. In fact, any young fellow who is temperate, willing to work, and loves righteousness, will find happiness sooner or later, if he does not weary in well doing.

NEW YORK STATE BEE-KEEPERS' ASSOCIATION.

REPORT OF COMMITTEE ON EXHIBITS.

S. VALENTINE & SON, of Hagerstown, Md., exhibit a hive called the "Success." It is a hive which we think will answer very well in the South, but will hardly serve us in this section, as it has chaff on only two sides.

A. D. Davis & Co., of Bradford, Vt., exhibit a hive which we consider the same as the "Bristol," introduced by A. E. Manum, the difference being that the frames run lengthwise of the hive instead of across the entrance, as does the Bristol; and we also consider the deep grooves in frames a strong objection, as it offers a hiding and breeding place for moths. We consider the hive a good and practical one, only too expensive for use for the extensive bee-keeper. Messrs. Davis & Co. also present a nucleus hive which we consider very good for shipping purposes.

Foster & Adams, of Utica, N. Y., exhibit two boxes of honey, mounted on a sort of whirligig, for which we can find no use.

Mr. Abbott, of England, exhibits a shipping-crate mounted on springs, in the form of our spring beds. This we think an admirable crate, and will find favor, if not too expensive. Mr. Abbott also exhibits several samples of packages for putting up extracted honey. These we consider very nice.

W. E. Clark, of Oriskany, N. Y., has a fine exhibit of smokers, honey-knives, one-piece sections, and bee-books, which we consider good.

J. C. Newman, of Peoria, N. Y., exhibits shipping-crates and separators, which we consider very nice.

Mr. E. Hastings, of Newport Mills, N. Y., exhibits a tin feeder, which is very novel; and although we have not tested it, and know of no one who has, we think it will prove a good thing.

F. A. Salisbury, of Syracuse, N. Y., exhibits a hive which we consider complicated, and not economical enough for practical use.

E. R. Newcomb, of Pleasant Valley, N. Y., has a large and very nice exhibit, among which is a chaff hive which we consider a practical one; still, we do not approve of the interior arrangement; otherwise the hives are well made, and there are a variety of styles which will suit almost any location. His shipping-crates, those in which the boxes are tiered, we do not consider good.

Aspinwall & Treadwell, of Barrytown, N. Y., have a very large and fine exhibit, among which is their "Electric" hive for the South. This we consider very good, and we also commend their chaff Electric hive for its simplicity and cheapness. Their knife-heater, for keeping the uncapping-knives warm while extracting, we pronounce very good and useful.

We also find on exhibition three styles of smokers, and we consider them all good. We also find four styles of uncapping-knives on exhibition. We consider them all good and have no preferences. There is also a good display of books devoted to bee-keeping, on exhibition; this we are much pleased to see.

Aspinwall & Treadwell also exhibit a wax-extractor which we consider very good, and the best on exhibition. We also find on exhibition several honey-extractors, among which is a reversible extractor, which we consider very good for a business run on a large scale; but for our use, the smaller extractors on exhibition we consider equally good, and will answer our purpose fully as well. We also find on exhibition two styles of comb foundation (flat and natural base), and we pronounce the natural base preferable for all purposes.

There is also on exhibition a photograph of some of our prominent bee-keepers, presented by Mr. Tuttle. We consider it nicely gotten up, and, as far as we know the likenesses, they are very good, and we think that Mr. Tuttle deserves a great deal of commendation. All of which your committee respectfully submits.

Pine Plains, N. Y.

G. H. KNICKERBOCKER.

BUMBLE-BEES, AGAIN.

REMINISCENCES AND OBSERVATIONS FROM G. M. DOOLITTLE.

IT is a very rare thing that I read any article in our bee-papers with more interest than I had in reading the one about bumble-bees, on page 181 of GLEANINGS, written by Prof. Cook.

When a boy there was no other one thing so interesting to me in all the realm of nature as was a nest of bumble-bees. I have watched them for hours in admiration and curiosity, as well as to spend hours in the "fun" (as all boys think it is) of trying to out-general the little fellows, to get the bit of precious nectar which the nest might contain. My regret now is, that this "fun" was often "death to the bees." I indorse all that Prof. Cook says of these bees, and would especially recommend to every reader what he says about encouraging the study of them and other insects. To encourage such study I want to tell the readers of GLEANINGS something about these bees, in addition to what Prof. Cook told us; and I desire that the professor and all shall carefully experiment the coming season to see whether I am right or not. Prof. Cook told us that the queen bumble-bee is the only one which lived over winter. This I am sure is right; but the point I wished to know most about was where and in what state did she pass the winter. Bro. Clarke will say, "hibernation," and I guess he is correct. But where? Well, until some one proves differently, I say in the earth. This I always believed, as in early boyhood I saw them coming out of the ground or from under a sod in spring when planting potatoes; but I was not so sure about it as I was ten years ago this spring. Ten years ago last fall I built my shop, and about one-fourth of the floor-space was left uncovered so as to set my steam-engine directly on the ground. One warm day the next May, while at work in the shop with closed doors, I heard a bumble-bee trying to fly down by the engine; and upon

going there it rose from near a little round hole in the ground, and flew to a window. At night I had three bumble-bees on the windows, and at no time had any of the doors or windows of the shop been left open during the days and weeks previous. Since then I have never found a bumble-bee in the shop except when I *knew* it came in at the door or window.

To digress a little. One season there was a nest of hornets under one of the bottom-boards of a hive of bees which sat on the ground. These hornets became so populous that they went and came nearly as fast as the bees from the hive. In October the hornets made no appearance at their entrance-hole, so the fore part of November I set the hive off the bottom-board and lifted said board up to see what kind of a home my friends had had. I found they had dug away and carried off the soil so that a hole had been excavated as large as a peck measure, and down in this hung their combs, almost without the usual paper outside seen on them when built on trees, buildings, etc., as they usually are. But the most interesting part of it to me was, that, down in the deepest part of the hole, was about a teacupful of queen hornets in such a state of hibernation that I could handle them at pleasure without the least signs of life. I looked at them occasionally all winter and early spring, when one day in May I saw a queen hornet; and upon going to my nest at this time all were gone. To return:

It is only the young queens of the bumble-bees that live over the winter, according to my observation, the mother dying of old age about the time young queens become fertilized. Prof. Cook says the bumble-bee queen lays her eggs on a mass of pollen. I find she covers her eggs with pollen, so that each egg is surrounded by pollen; and when the larva hatches it eats itself out of this pollen, when the cell is formed, as he says. Of these eggs, only five to eight are at first laid (usually six), all of which are the small workers spoken of by the professor. Just previous to the hatching of these first workers, more eggs are inclosed in pollen; and, if all is prosperous, still others, till into August, and all of these eggs hatch out the larger-sized workers spoken of by the older writers. They are not the drones nor the queens, friend Cook, as they will soon show you by defending the nest, for the young queens never make any defense, except in the spring. Next, the eggs are laid for the drones, and then for the queens. The number laid seems to be governed by the strength of the little colony. Sometimes not over two or three of each, and again from 20 to 50.

In this locality there are at least six different varieties of these bees. A smallish bee, about the size of a cranberry, with a bright lemon-colored abdomen tipped with black, which appears first in spring, and always, as far as I have observed, build their nest in the ground. These are the ones which sing so sweetly while working on roses. Next a smaller kind having an abdomen of lemon and red. There is another very nearly like this last, except that the color is lemon and black. Then we have one about one-third larger than the first, whose abdomen is of a rusty orange color. These last three always, as far as I have ever seen, take an old mouse-nest top of the ground for their home. Next we have a bee about the size of the last, whose abdomen is nearly white, always called "white-backed bees" here, and for stinging qualities they are

ahead of any of them. Then, last of all, is a very large bee, the queens apparently attaining the size of a man's thumb up to first joint. These in color resemble the first. The last two are those oftenest found in buildings, but are not above taking an old mouse-nest for a home. The first four are not very numerous. The sixth is quite common, while the fifth equals all of the other five in regard to numbers.

Friend Root speaks of learning to tell those that do not sting. This may be a hard matter with some, but I can tell a drone bumble-bee as well as our drones from the hive. The drones from the first and last named, when mature, go in the shade of trees and sit on a fence-stake or mullein-top, and wait for the queens to come along. These are called "shade-bees" here. If you can catch such a bee you need have no fears of its stinging, for the bumble-bee drones have no sting. I have spent hours throwing bits of sticks or dirt past and near these bees, to see them chase and lay hold of them, for such a procedure is often more amusing on hot days in August than cutting thistles and weeds out of corn.

The drones of the fourth and fifth variety come out in large numbers, and swarm over the nest from sunrise till 9 or 10 o'clock on still mornings, and the knowledge of this fact has helped me to find hundreds of their nests. Here they chase each other about while waiting for the queens to mature ready for flight. If you want to see all about it, when you find drones thus sporting above a nest, take a long pole or pitch-fork, and suddenly break their nest open so as to get the queens to take wing. I have done so many times. You will have to do this carefully on your part, unless you are fixed sting-proof, for the workers will resent it with all fury.

One thing I desire to call attention to: These bees last spoken of exist and have existed for all time by in-and-in breeding. The others are always crossing, yet those which are bred in and in thrive beyond all the others. Will this apply to our honey-bees?

G. M. DOOLITTLE.

Borodino, N. Y., March, 1887.

Thanks, friend D., for the additional facts you furnish. I should like to have Prof. Cook tell us how now nearly your deductions agree with the generally accepted facts in reference to bumble-bees. I have often seen the kind you mention, that will post themselves in the shade, and I have also seen them chase after dirt, sticks, etc., or even insects. I guess Prof. Cook will have to reply to your last paragraph.

CYPRIAN BEES.

THEIR VICIOUS HABITS GRAPHICALLY DESCRIBED BY AN ENGLISHMAN.

FROM the *British Bee Journal* of March 15, page 20, we clip the following from the pen of our friend James A. Abbott, to whom reference has formerly been made. The facts related by Mr. A. accord very well with our own experience with the *pure* Cyprians, and so we are the more ready to accept it as true.

I have found that, while the Cyprians are in small colonies only, or while the hives contain only young bees, they may be easily handled, but, that when-

ever a stock is in condition to work a super or store surplus honey it is as dangerous to handle as a bombshell.

As I at first devoted all my spare time to raising queens I had no strong stocks to handle, and therefore could not fully appreciate their temper, but my subsequent experience is as much as I want. I remember one operation in particular. I had to remove a queen from a full colony, and felt determined that it should have every chance of behaving well. Having put on a new straw hat and veil, and a freshly washed holland jacket, made on purpose for handling bees, with tightly fitting waist-band and belt, the attack was made very much as directed by Mr. Simmins, without smoke.

The combs were handled in turn, the queen caught and carefully put in her box; but here the trouble began. The bees suddenly found some flaw in my management, though I can not say where; and though I had only to put the combs up together and replace the quilt, I was forced to retire twice before I could do so. The bees rose in a cloud and attacked me on all sides. Stings on the hands did not much matter, but when busybodies force themselves between one's coat-buttons and explore until they find a tender spot, it is more than a regular bee-man cares about. The second attack was made with the addition of string tied round the ankles, india-rubber gloves, and a smoker, but even thus armed I could not stay within range long enough to put on the quilt. Their resentment was now at its height, and a poor sparrow that settled near them was violently attacked and barely escaped with his life. Even when I considered all was over, and I had, after rest and refreshment, retired to my bedroom, an unsuccessful pioneer flew out on the removal of my waist-coat and attacked me with spirit. I do not say that Cyprian bees can not be handled any more than I would say tigers can not be tamed or bombshells charged, for I have sometimes managed them very pleasantly, but I would strongly advise any one who has any thing to do with them to be prepared for a desperate battle at any moment.

Southall, London.

J. A. ABBOTT.

We have not in all cases found the race as vicious as given above; but one must not be surprised if the Cyprians which he has to handle should take it into their heads to behave just as described above. If they don't happen to find a "flaw" in the management, all well and good; but if the apiarist has unconsciously made a wrong move in their judgment, they will apprise him of the fact right speedily.

WOMEN AS BEE-KEEPERS.

REASONS OF FAILURE.

THE reason some women fail in bee-keeping is, they do not dress warm enough, and so take cold; or not cool enough, and so overheat. They don't release themselves from other cares enough, and so neglect the bees, or else overwork.

They don't have things handy to do work with, and so have to do a great deal of work to accomplish a little.

They don't keep the smoker in order, and so bees drive them or sting them badly.

They don't have things in readiness, and so do things out of season, just a little behind time with every thing, too late in building up colonies strong in the spring in time to get the white-clover honey; too late in putting on sections, and so bees get the swarming fever; too late in preparing for swarming, and so are driven almost to death; too late in getting the honey off until the honey-harvest is over and bees rob terribly; too late in fitting up for winter, and so bees have to go neglected, and die in winter, and then these women say, "Bee-keeping doesn't pay."

I find I need to watch against taking cold more than overwork, as much of our bee-work is done sitting or standing in the open air. When we have a good many bees we need occasionally to work in damp, cool, or windy weather. I have been nearly all my life troubled with weak lungs, being given up as in the last stages of consumption when at the age of 19 and 20, then in later years could hardly live through the cold winters on account of having pneumonia so often.

All lady bee-keepers should have rubber boots; They should put on extra clothing, a small hood under the bee-hat, and a tight-fitting cloak of light-colored heavy goods to wear in cool and damp weather. They should fix themselves up comfortably, so a bee can't crawl inside their clothing, and they will enjoy their work much more. They should not do as a woman did I once knew, who took great pains to fasten her hat on securely, and then rolled her split-open sleeves up to her shoulders. With her dress partly unfastened, she pitched into her bees, and they pitched into her in so lively a manner she thought "bee-keeping did not pay," and so borrowed our extractor and took all their honey away in the fall. She wondered why her bees died in winter.

MRS. L. C. AXTELL.

Roseville, Illinois.

I heartily indorse your remarks on good and comfortable clothing for your sex, Mrs. A., especially where they undertake open-air work like bee-keeping, etc.; and I hope no lady will be deterred from using rubber boots, by the thought that it may be unlady-like. It is always ladylike to be well protected. My wife has got in quite a habit lately of using my own rubber boots when she has occasion to go to the barn, and she says they are a real comfort. Most shoestores nowadays have light rubber boots specially for ladies. Throat troubles, and perhaps many cases of consumption might be kept away by proper care and the use of proper precautions when going out in the wet and damp weather.

T-SUPER FEEDER.

DR. C. C. MILLER TELLS US HOW TO FEED BEES.

I SHOULD say there are, in all reason, enough feeders without a new one; but I wanted one that would cost little, hold much, and be conveniently used as an accompaniment to the T super, so I submit the one I have planned. It is made of pine wood, and is nailed together with $\frac{3}{8}$ -in. wire nails. The materials are:

- 1 piece 15 x 11 $\frac{1}{4}$ x $\frac{1}{4}$ (a)
- 2 " 11 $\frac{1}{4}$ x 4 $\frac{1}{2}$ x $\frac{1}{4}$ (b)
- 2 " 14 x 2 $\frac{1}{2}$ x $\frac{1}{4}$ (c)
- 2 " 14 $\frac{1}{4}$ x 2 $\frac{1}{2}$ x $\frac{1}{4}$ (d)
- 4 " 14 $\frac{1}{2}$ x 3 $\frac{3}{4}$ x $\frac{3}{8}$ (e)

First a plain box is made by taking two of the pieces *e* for sides, and nailing upon them the two pieces *b* for ends, and then nailing on the piece *a* for a bottom. As this is to be a water-tight box, the nails should be put in quite thickly. I have put them in about $\frac{3}{8}$ of an inch apart, and I'm not sure whether a different distance would be any better. In order to make them hold tighter I slant each nail in driving, slanting the first nail one way and the next the other. Barbed nails (if such small nails are ever barbed) might be better, and

would not need to be slanted in nailing. Allow me to say, in passing, that the principal objection to the wire nails is their smoothness, which makes them pull out more easily. If barbed, this difficulty is overcome; and a simple way to have them perhaps even better than barbed is merely to let them get rusted. A rusted wire nail will hold very tight. In nailing the bottom on to the side pieces *e*, the nails need not be more than half as close together, as the grain of the wood here runs in such direction that such close nailing is not needed. The remaining two pieces, *c*, are to be nailed in the box, one parallel to each of the side-pieces, leaving between it and the side piece a space of $\frac{3}{8}$ inch. It will be seen that the ends of the box are $\frac{3}{8}$ of an inch higher than the sides, and the two inside pieces, *c*, that are afterward added, are to come flush with the upper edge of the ends, and this will leave a space of $\frac{3}{8}$ of an inch between these inside pieces and the bottom. Very few nails are needed to fasten these inside pieces, as no strain comes upon them, and they are not to be water-tight.

Fig. 1 represents a cross-section, showing how the end-board is nailed on the pieces *e*.

Now on each side nail a piece, *c*, upon the upper edge of the inside piece *e*, making the inside edge of *d* come flush with the inside surface of *e*. Only a few nails, say 5, are needed for this. Now, upon the upper edge of each end of the box nail the piece *c*, by driving three or four nails at each corner, making these nails (if not rusted) slant in opposite directions, as they are to bear the whole weight of the box, and all its contents. These three nails at each corner should be close together, per-

DIAGRAMS OF DR. MILLER'S T-SUPER FEEDER.

haps $\frac{1}{4}$ of an inch apart. Fig. 2 shows the position the pieces *c* and *d* occupy when nailed on the box.

The feeder is now complete, except that a strip of wire cloth must be nailed upon the outside lower edge of the inside piece *c*, to prevent the bees from crawling through under this board. Of course, this strip of wire cloth must come clear down to the bottom of the box, and it should have been nailed upon *e* before putting the box together. For convenience in making, it is probably

better that the inside pieces, *e*, have the end pieces nailed on them at the same time they are nailed on the sides before the bottom is nailed on.

The feeder can now be hung in a T super, and is ready for operation. At each side, between the walls of the super and the box, is a space of about 7-16 of an inch, up which the bees can pass and be admitted directly to the feed. As the feed is gradually consumed, the bees can follow down the $\frac{3}{4}$ -inch space, in which there is no danger of drowning, but the wire cloth at the bottom prevents entrance to the inside or central part of the feeder.

Now as to the advantages and disadvantages. They ought not to cost, if made in quantity, more than 10 cts. each, ready to nail. The feeder holds about 10 qts. When not in a super it is a rather flimsy affair as to the upper pieces, which would be easily split off. Perhaps if made of thicker stuff it would be stronger; but when in use it is sufficiently strong. When first filled it leaks. This can be remedied by running hot wax around the corners. I would, however, just as soon have it leak, as it leaks directly on the bees. The feed can not be taken as rapidly as from a number of Simplicity feeders placed on the frames, as the latter present a larger surface to which the bees have access. The capacity in this respect could be doubled by having the inside piece, *e*, $1\frac{1}{2}$ in. distant from the outside, and another piece half way between the two with a $\frac{3}{4}$ space both top and bottom. On the other hand, this feeder is filled much more readily than the Simplicities, as the super cover, when lifted off, reveals an open space, $11\frac{1}{4} \times 9$ inches, into which the feed can be poured, and no bee from within can get into this part. The feeder, of course, could be nailed fast to the super, and then there would be nothing flimsy about it, but it would cost more. The feeder is not likely to be needed at a time when supers are in use otherwise.

C. C. MILLER.

Very good, doctor; but I wonder if you knew how serious a matter it is to recommend an implement for bee culture without first counting the troubles and mishaps that might possibly result by putting it in the hands of the inexperienced. First, you say it would not make any difference if it does leak, as it leaks directly on to the bees. Now, with a strong colony, with the entrance properly contracted, perhaps it would not do any particular harm; but with a colony rather weak (and the colonies that need feeding are many times of this class), before you know it the feed would be running out at the entrance, or over the bottom-boards, at the sides of the hive. Robbers would get hold of it, and the result might be that we should have more sensational articles in the papers about people being driven from the streets, and horses being stung to death, etc. I think you had better wax the joints, and then try the feeder with water. If it holds water it will hold syrup. Another thing: As you have arranged it, the bottom of your feeder will be nearly or quite an inch above the honey-board. I suppose, of course, you meant to leave the honey-board left on. Now, in using such a large quantity of feed as this feeder will hold, the bees will start comb-building with a vengeance, and it seems to me they would be very likely to build combs

between the feeder and the honey-board. Perhaps somebody who has tried it can tell us about this. I grant, the feeder would be a very convenient one, and you could give the colony a great abundance with very little trouble. From what experience I have had, however, I would not think of using such a feeder unless an outside shell be placed over it and the super. Inside of a chaff hive or inside of a Simplicity hive it would do very nicely; but if there are cracks where the bees can see through and smell the feed, they will often (at least in our apiary) bite away the solid wood until they can squeeze through where the cracks and openings are.

A LETTER FROM ONE OF OUR MISSIONARIES IN CHINA.

SALT FOR BEES; SOME FACTS IN REGARD TO THE MATTER, FROM FAR-AWAY CHINA.

DEAR FRIEND ROOT:—While on my way from Foochow to this place last November I noticed a thing which seemed to me to throw light on the question of why bees should suck the moisture from dirty places. We were traveling by boat; and as there are many rapids in the river, the boatmen sometimes row, sometimes pole, and sometimes track. We had reached the head of a long stretch of still water, where all the boats on the river had to change from rowing to tracking. The landing-place was a large bank of clean sharp sand, and my wife, daughter, and I got off for a walk, as the boats make such slow progress that we can walk on at our leisure, and sit down and wait for them to catch up. As we ascended the sand-bank our little girl called my attention to an irregular patch on the sand, eight or ten inches broad, and brown with bees. They all had their tongues thrust out, eagerly sucking something from the sand, and paid no attention to our presence, not even when I knelt down and brought my nose close to them to see if there was any odor to show what it was that proved so attractive to them. On looking further we found three or four such patches of bees; and in every case the sand smelled of urine. In fact, the bees were eagerly sucking fresh urine from the clean sharp sand. The bees were larger, and of a little lighter brown, than most of the honey-bees I had seen before in China, so I asked the Chinese what those insects were. They replied "T'ang fung;" i. e., sugar-wasps. The correct Chinese would have been, "mih fung," or honey-wasps, but the common people often call them sugar-wasps.

There is one other honey-eating insect which, like the bee, has this same fondness for dirty puddles, and this is the butterfly. The nectar of flowers is his principal food. Now, it is a well-known fact that certain minerals enter into the composition of all living tissues, such as salt, sulphur, lime, and phosphorus. These minerals exist in minute quantities in most articles of food, so that the supply can be kept up without our specially eating them. But it is very doubtful if this is true of the nectar of flowers; and if not, it is easy to see why bees and butterflies should be so fond of excrements, which are rich in these mineral substances.

Some years ago we tried the plan of keeping a cow—a Chinese cow—and one of the ladies tried to

make friends with the animal (which did not take kindly to foreigners) by giving her salt; but the creature did not seem to know what it was. The Chinese do not give their cattle clear salt, but mix a very little with rice water to give them. There have been found some Indians who, when first given salt things, disliked them, saying it made their mouths smart. Nevertheless, we have high authority for holding that "salt is good."

Shanghai, China, Feb., 1887. J. E. WALKER.

Friend W., this matter has been brought up many times before, and you are, without question, right in regard to it. Unless bees find access to salt in some way, they are quite sure to get it from the sources named. In our apiary we keep a large glass jar full of salt water in the summer time. This is inverted on a grooved board or some other substantial substitute, so the bees have convenient access to it whenever they want it.

are bothered with the moth, while in communities in which there are no bees except Italians, the bee-moth is almost extinct.

Some of the friends have reported that their black and hybrid bees were more docile than their Italians. Perhaps those bees which they call Italians are a cross between Italians and Cyprians or Syrians. No one but an expert can tell the difference between Italians and a cross with those races. We did not hear much about the Italians being so cross until those new races were introduced in this country, except a few complaints where hybrids were called Italians.

G. D. BLACK.

Brandon, Iowa, March 21, 1887.

EMPTYING T SUPERS.

CAN MILLER'S PLAN BE SIMPLIFIED?

YOU say, Ernest, on page 249, "I want to ask if it would not be possible for you to simplify your device for emptying the Tsuper. Why not dispense with the hive-cover?" If a change could be made in making a Tsuper that would make each super cost 5 cents less, it would be worth studying over and experimenting about for days. In an apiary of 100 colonies it would be a matter of \$15 or so; whereas in the same apiary the saving of 5 cts. on each bearing-board would be a matter of only 10 cents. In other words, where only one or two articles of a kind are made, and to be used over and over again, the question is not so much how cheaply or simply can they be made? as, how can they be made so as to do the most rapid and satisfactory work? If I knew how to get up an arrangement that would cost much more, and yet take out a superful of sections in quicker time, I would cheerfully throw away the old arrangement and make new. It is possible the device might be simplified. I used the hive-cover, partly because I had a lot of deep hive-covers that I had thrown aside, because I could not afford to use such heavy covers. I am not sure, however, that it, or a box similar to it, can be dispensed with. The essential thing is the one side and end; in other words, the one corner of the box, with an arrangement to quickly and surely place the bearing-board in its exact position, and then as quickly and surely place the super in exactly the right position over the bearing-board.

The arrangement you propose is, so far as it goes, just about the same as I use, only I have mine fastened to the hive-cover. I would rather have the hive-cover out of the way if it would work just as well; and after you have placed the super properly on your box, I think you can make a little quicker work without the hive-cover. But the necessity for the hive-cover appears when you come to place the super, "being careful," as you say, "to get it squarely over." The best you can do, I think it will take you at least one minute to put the super in its proper place, and you will then be obliged to stoop and look under each super; whereas, with the hive-cover there is no need of being "careful," but in one second of time you can pull the super to its place, and be sure that it is just right. The bearing-board would be easier made, as you suggest; but I am afraid the edge of the board would split off in a little time; and, moreover, the board would be likely to warp.

C. C. MILLER.

Marengo, Ill.

ABOUT THAT REPORT ON PAGE 184.

ITALIANS AND HYBRIDS.

I DID not intend to convey the idea that Italians are better honey-gatherers than hybrids. All other circumstances being equal, I believe that the progeny of an Italian queen mated with a black drone will produce as much honey as Italians when there is plenty of honey to be gathered; but when honey is scarce, the hybrids are more apt to spend their time buzzing around the honey-house windows, or trying to steal from some weak colony. My hybrids were worked for comb honey, and the Italians for extracted honey, which will account for part of the great difference in the amount of honey gathered. The average would be 220 lbs., not 260 lbs. The 30 colonies of hybrids were wintered in the cellar, while part of the Italians were wintered in chaff hives. When the honey-harvest commenced, those in chaff hives were two weeks ahead of the others.

The following are some of the reasons why I prefer the Italian bees rather than hybrids:

1. Stability of features and characteristics. It is a well-known fact, that it is a very difficult matter to fix the characteristics of a hybrid or cross, in either the animal or vegetable kingdom. We might establish an apiary of hybrids of the first cross, having nearly the same markings and characteristics; but in a few years we should have bees in all the different degrees of purity, between Italians and blacks, and possessing all the different characteristics of the two races; while if they had been Italians, or any other pure race, they would, at the end of a few years, all have the same markings and characteristics that they had when the apiary was established.

2. Italians are proof against the bee-moth, while some hybrids are not. A few years ago, before I Italianized my bees, I had to fumigate my surplus combs, and the chickens breakfasted on the mutilated brood which the bees threw out during the night; but all that is changed. I do not think that I saw more than a dozen moth-worms in my apiary last summer.

3. The comb-honey that I bought of parties having black and hybrid bees was considerably damaged by moth-worms. I notice that friend France and others, who are extolling black and hybrid bees,

I give up, friend Miller; you are right. Your explanation, I think, clearly shows that the hive-cover, or something very similar, is simply a matter of necessity. These little minutes in the height of the honey-flow are too costly to lose, when a little additional expense of ten or fifteen cents possibly might save them.

CONTRACTION, AND HOW TO MAN-AGE IT.

ALSO SOME VALUABLE THOUGHTS AND SUGGESTIONS IN REGARD TO THE VITAL QUESTIONS BEFORE US.

FRIEND ROOT:—GLEANINGS for March 15th is at hand, and is so brimful of good and timely ideas that I am constrained to write and express my satisfaction. We are all much pleased with the glimpse you give us of your "great hive" filled with busy, earnest workers, and heartily wish you continued success and prosperity at the Home of the Honey-Bees.

In regard to taking bees from the cellar too early, Dr. Miller comes forward with a bit of his ripe and rich experience that ought to be well heeded. He is right in saying, "Better too late than too early." Surely if we have control of our cellar temperature, as we ought, the bees are much better there than outside, until settled warm weather. By the way, I am much gratified to see Dr. Miller and others leading you out of the woods on the comb-honey-super question; but I fear you are hardly clear of the shadows, so long as you cling to the 10-frame brood-chamber with super to match, and use an outside cover over the comb-honey arrangement. Are you not aware of the fact, that the great majority of our leading practical and progressive apiarists are abandoning the large brood-chambers of ten and twenty years ago, and using eight, and even less, L. frames for both comb and extracted honey? It behooves the editor of so spicy a journal as GLEANINGS to lead and not follow, in this progressive march.

Allow me to assure Dr. Miller, that the principle of contraction is permanent. It has "come to stay," but we have learned that we must have brood under the whole comb-honey super, and so we contract horizontally—the only true and logical method. I left over 50 colonies on five L. frames the entire season, from April to October, last year, and never had better or larger swarms, or got better results, than I did from these contracted hives. When put into winter quarters they were much stronger in bees than I care to have them. Now that you have indorsed and adopted the slatted honey-board, the bee-space above sections, and the plain board cover with square butting joints, you are traveling in the right direction, and will surely go the whole distance before you stop. Where hives are left unprotected in the sun, the outside cover is right and proper; but when a large shade-board, with air-space between it and cover, is used, the thin single-walled cases are cooler and better. Remember, that it is largely the inside heat of the hive that we want to escape, in hot weather.

Adam Grimm, you know, thought it necessary to slip supers by each other to provide this ventilation. A properly made square butting joint will not admit wind or rain, and, as Prof. Cook says, is the proper way to construct these joints. I could

not now be persuaded to again use a telescopic joint.

Friend Heddon has been five or more years ahead of us in this matter. I use the Heddon non-separator case, and find it cheap, strong, and neat. I also have some 200 of his new invertible wide-frame supers. These latter have many advantages over others, but are rather costly and complicated. I never did like wide frames, you know. It seems to me there is a great future for the tin T super. I shall try a few of them this season, and, if desirable, will use them largely hereafter; if not, I will return to the old-style Heddon case, which is hard to beat.

Terry's book on the winter care of horses, and the A B C of Potato Culture, ought to be in the hands of every bee-keeper and farmer, and we owe you a vote of thanks for placing them within our grasp. My 150 colonies are wintering nicely in the cellar, and loss will be slight. D. FURNESS.

St. Louis, Mo., March, 1887.

Thank you, friend F., for your kind words and kind suggestions. I am afraid we have been getting a little in the shadow since we stopped raising honey and confined our attention solely to raising bees and queens. There is considerable difference of opinion, even in this matter of contraction; but if we can cut our colonies down to half space in the brood-chamber, just before we work for comb honey, very likely a half brood-chamber, or something on the style of Heddon's latest hive, may be what is needed. I have recently had considerable talk with Prof. Cook and W. Z. Hutchinson in regard to the matter. Your large shade-board, with an air-space between it and the cover, is all right to keep off the sun's heat; but when we wish to protect the comb-builders during cool nights, my experiments indicated that the outer shell was very valuable. As Dr. Miller is with us just now, he answers a part of your letter as follows:

Friend Furness, as I happen to be at the "Home of the Honey-Bees," Mr. Root has kindly shown me your letter, and allows me a word of reply. You have put a thought, almost new, into my head. It is, that it is better to continue the bees quite late in the cellar, where we shall be certain about them, than to take them out where it will be uncertain, balancing between two possibilities—one, that they may be somewhat better off; the other, that they may be much worse.

As to the size of the brood-chambers, there is so much to be considered that it may be well to be a little careful about making changes. You may be right and you may be wrong about the matter of contraction; but I must confess that, from what I have read and from what I have experimented, there is much uncertainty in my mind on the whole subject. For those of us who use the regular Langstroth size of frame, or any thing near it, if we practice contracting we certainly do not need room for 10 frames during the time of contraction; but at other times it so often happens that I need more room than I am not sure I care to have my hives less than 10 frames. It is convenient, many times, to put an extra frame or two in the side of a hive where the bees may care for it. Then if only eight frames or less are in the hive, it makes it practically a side-opening hive; and whilst I could not tolerate a side-opening hive, I am glad to have

the advantage of easily lifting out the division-board and the first frame without disturbing any other frame. Then the 10-frame hive can have a tight division-board in the center, and be used for two colonies, and possibly you might like this if you tried it.

I also had most of my colonies on no more than five L. frames from April to October; but for all that, I want a hive capable of holding ten frames some parts of the year. C. C. MILLER.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

HOW TO FASTEN PIECES OF COMB IN THE SECTIONS.

IN a number of GLEANINGS in the latter part of last year the question was asked, "What is comb worth per pound, new and white, for starters in sections?" Your reply was, \$1.00,

but for trouble of fastening in. Let me say, it is very easy after you know how. In swarming, and in the honey season, I keep almost every day hot wax on hand. It is kept so by having a box as high as a lamp and chimney. Your wax being hot, take a turkey-tail or wing-feather, of good size. Your pieces of comb should be cut the size you wish. Your sections should be in the frames (I use wide frames). Dip the feather in hot wax, and paint the inside of the section. Next set the piece of comb on the feather. Holding the former with the left hand, draw out the feather. As the wax will set quick, the thing is done.

Your wax should be hot enough so the feather slips out easily and slick. You can put the pieces of comb in this way faster than you can put in comb foundation by any method. I have put in thousands, and never knew of one to drop out. I have thought for two or three years to give it to the public. I never saw any thing like it in print.

Brush Creek, Ia. B. F. LITTLE.

MOVING BEES NORTH AND SOUTH TO CATCH THE HONEY-FLOW, NOT PRACTICABLE.

Tell friend Baldridge not to think of that "North and South project" unless he wants to lose more than he makes. I know him to be an expert and able bee-keeper, for he had charge of a lot of my bees a few years ago, and I know of no one who would be more apt to succeed than he; but I would earnestly advise all contemplating such an enterprise, not to do it, for the extra labor, extra expense, extra care, extra anxiety, and extra risk can not be repaid, even if very successful in producing three crops of honey, which is at best doubtful. I have been through it, and I know from personal experience what I am talking about; and if I wished any one ill, I could not accomplish it better than by persuading him to do just what friend Baldridge proposes to do.

Belleville, Ill., Feb. 3, 1887.

E. T. FLANAGAN.

MIXING ALSIKE WITH TIMOTHY.

In some of the late articles in GLEANINGS on alsike, reference is made to mixing it with timothy for a hay crop. This is an important point, worthy of more attention than it has received, particularly from bee-keeping farmers, who do not care to grow it for seed. Our experience justifies us in recommending very highly a mixture of alsike and timo-

thy. It makes the choicest and most nutritious kind of hay. It is much better than red clover to mix with timothy, as it is still in prime condition to cut for hay when the timothy is just right, and is not damaged by rain more than timothy is. We sow a mixture of one-half peck of timothy and three pounds of alsike per acre. Never sow less than six pounds of alsike per acre, when you sow it alone for a seed crop. It will pay to sow alsike for bee-pasturage, even if there is an abundance of white clover, as it yields honey much more abundantly, and the bees therefore prefer working on it.

Urbana, O., Feb. 24, 1887. JOHN C. BARNETT.

CLIPPING QUEENS ON THE COMB.

It seems, to Mr. Axtell and myself, that catching the queens by the thorax or head, with the left hand, either with naked fingers or in a sack, is not the best way. We used to do so, but lost more queens than by the present way of taking the comb she is on. We gently set the comb in a slanting position against the back of the hive. When the queen goes to crawling up (never down), then quietly catch a wing with the left hand and clip it off is the best way. Sometimes it is more convenient to clip the other wing. Never hurry; one is apt to get nervous, and in a hurry; but there is no need of it. It is better to clip her on the comb with the bees, as she and they are more quiet. S. J. W. AXTELL.

Roseville, Ill., March 9, 1887.

A GOOD WORD FOR MRS. LIZZIE COTTON AND HER SYSTEM.

Permit me, through the columns of GLEANINGS, to make a few statements with reference to Mrs. L. E. Cotton, of West Gorham, Me., and her system of bee-management. I purchased of her, in the spring of 1884, her book, entitled "New System of Bee-Management," and I am ready to state that, if I could not get another copy of it, I would not part with it for ten dollars. I have followed her plan for two years, and have had splendid success, both in wintering and in securing surplus honey. I consider her feeder superior to any other arrangement I have yet seen. I am now feeding my bees with a view of increasing my number of stocks. I have nine, and I wish to secure from each of them two strong stocks. I think that her whole system of management is based on reason and experience. I am aware that she has been termed a fraud and swindler; but in her dealings with me she has been perfectly honest. W. M. ALLEN.

Trempealeau, Wis., Mar. 28, 1887.

I am glad to get such a good report from Mrs. Cotton, friend A., for there has been a great deal of dissatisfaction and fault-finding; and some letters are just now at hand, making complaint. These have, however, been referred directly to Mrs. C., at her own request.

THE BROWN BEES OF ARKANSAS: LARGE SIZE OF DRONE-CELLS.

There has been much said lately about the black, or brown bee. The brown bee of this country is certainly different from those described by Doolittle and others. I believe it possible that there is not a pure race of bees in the world at present; and very likely the different strains of black bees are more the cause of the different opinions and results than locality. To show you that these are not the little black bees, I by this mail send you a sample of these natural-built combs. You can see

the drone-comb is 1 cells to 2 inches, and the worker is in proportion. These bees are almost equal to the bumble-bee on red clover; are moth-proof, very prolific, and swarming is very easily controlled. I wish you could see some of the white comb honey that has been in the hives since last summer. I have handled these bees 30 years, and no sign of any disease has been among them. They are excellent honey-gatherers, and seal it quick and white. The first cross of these bees with Italians produces very beautiful two and three banded bees. If you wish I will give you a full account of these bees, with a sample queen and all. I think, to breed from one of these queens in your apiary would be the best and cheapest way for you to furnish good hybrids. I have only one Carniolan queen. Who wants her? F. C. MORROW.

Wallaceburg, Ark., March 21, 1887.

I will say to our readers, that the drone-comb which our friend sends has $3\frac{1}{2}$ cells to the inch. Ordinary drone comb has 4 cells to the inch; but if our friend will turn to pages 147-8 of the A B C book he will see that it is not uncommon to find drone comb with cells a little larger than usual. The worker-comb cells sent are about the same size as ordinary.

REVERSING; ZINC HONEY-BOARDS, ETC.

I have 7 swarms of bees wintering in good shape. They have been covered with snow till lately. As they are in chaff hives, the snow only made them warmer. I have adopted for future use a frame $9 \times 13\frac{1}{4}$, outside measure, combined with your reversing device, and am well pleased with them. Reversing, even in a four or five frame nucleus, with me, causes all the unsealed honey to be carried to each outside frame. The middle ones are then filled with brood. I hived one swarm on eight empty frames and one frame of brood, under one of your zinc honey-boards, and they made 104 lbs. of comb honey in pound sections. The bees also filled the hive so full of new comb and honey that, on the first of September, I had to take out two cards of honey, and give them empty combs for the queen to lay in. Others, just as good in every way, made only from 50 to 75 lbs. in sections. I shall use zinc honey-boards altogether this season.

Instead of a "Hill Device," I use under the cushion those thin, oblong wooden butter-dishes that they use at the groceries. They cost next to nothing, and, turned upside down on the frames, they work first rate.

C. A. RICKETSON.

Quincy, Branch Co., Mich., Feb. 11, 1887.

CELLAR WINTERING; PREVENTING INCREASE.

I put in the cellar last fall 92 colonies in fair condition, and to-day I have the same number in the best of condition, keeping them at 45° till Feb. 1, and now at 50° . My experience is, not too much ventilation, as it makes the bees uneasy.

HOW TO PREVENT ROBBING.

In the first place, I find it a good idea to set bees out of the cellar in the evening, as they get settled down by morning, and protect their hives better by so doing.

WORKING BEES IN SWARMING TIME, TO PREVENT INCREASE.

I first allow them all the room they want, giving them empty sections to keep them back from swarming, as much as possible. When the first swarm comes forth I take a half of its frames

and replace with empty ones; remove the full frames to the new hive, put in a division-board next to the swarm. When No. 2 swarms, put it in No. 1, first shaking No. 2 up thoroughly. When No. 3 swarms, put it into No. 2, and so on throughout the season. I find this the best plan to prevent increase, and is less work.

JOHN ELLINGER.

Hopkins Station, Allegan Co., Mich., Mar. 17.

NOTES AND QUERIES.

OIL OF ANISE.

WHY not get a small vial of oil of anise, and drop one or two drops on rye meal? I believe the bees could be induced to work with the anise even on sawdust. The bees love anise, and bee-hunters would do well to use it while hunting bees.

J. H. ROBERTS.

School Hill, Wis., Mar. 17, 1887.

[Friend R., oil of anise has been used for such purposes as well as for inducing bees to start work in bee-hunting. In the vicinity of our apiary, however, a little bit of refuse comb honey always starts the bees quick enough without any anise or any thing of the sort.]

WIDE VS. NARROW TOP-BARS.

I find 11-12 of an inch to answer my purpose best. I made a few last spring $1\frac{1}{2}$ in., and I find them a nuisance; $\frac{3}{4}$ is rather narrow, in times of rapid honey-flow; but at all other times they do well.

W. D. ANDERSON.

St. Thomas, Ont., Can., Mar. 21, 1887.

IN FAVOR OF TEN-CENT SECTIONS OF HONEY.

I think the 10-cent sections of honey would sell well here. I sold all my honey early and readily at $12\frac{1}{2}$ cts. per box, $4\frac{1}{4} \times 4\frac{1}{4} \times 2$; but I found, by what little experience I had, that 10-cent packages would have sold much more readily. I am located in an iron-mining country. They are a class of people who have not much ready cash, but can find 10 cts. when they could not be persuaded to pay 15 or 20 for a package that contained more in proportion for the money.

D. A. MASE.

Mt. Hope, N. J., Feb. 21, 1887.

HOW TO RAISE THE TEMPERATURE IN A CELLAR ECONOMICALLY.

On p. 186, Mar. 1, Mr. C. D. Black tells how to warm a cellar with water. I think I have a better plan. I have a large kerosene-lamp, holding about a quart, with a round wick, which I light, put on a shade, and set it in the cellar, placing shade-boards so that the light will not shine upon the hives. It will raise the temperature from 4 to 6 degrees in as many hours. My cellar is 12 by 14 ft. in clear.

H. J. NORTHRUP.

Lansingburg, N. Y., March 5, 1887.

COMB HONEY IN MARCH.

We placed upon our table, the 20th of March, section honey nearly capped, and the finest we have ever seen here. The flavor is the best, and thick, white, No. 1 honey. We have a quantity of this honey, comb and extracted. The frames we may extract later. This morning the last cold wave from the frozen hyperborean regions reached us—temperature 50° at sunrise. No bees out. There was a good rain the 20th. We are sending out some queens to Ohio and Pennsylvania. No loss heard of. The weather is cool and fine.

J. W. K. SHAW & Co.,

Loreauville, Iberia Parish, La., March 21, 1887.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows: viz.: *Sheer Off, Silver Keys, The Giant-Killer*; or, *The Roby Family, Rescued from Egypt, Pilgrim's Progress, and Ten Nights in a Bar-Room*. We have also *Our Homes, Part I., and Our Homes, Part II.* Besides the above books, you may have a photograph of our old house apary, and a photograph of our own apary, both taken a great many years ago. In the former is a picture of Novice, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

CONDUCTED BY ERNEST R. ROOT.

THE BOYS' BEE-HIVE FACTORY.

WINDMILLS AS A MOTIVE POWER FOR HIVE-MAKING.

IF there is one thing above another that makes a boy all out of patience, it is waiting for a thing when he thinks it ought to come *right away*. Every now and then that evening, Sam would go into the back yard and peer at the windmill on the barn, to discover, if possible, whether "that thing was going or not." He began to complain about there being no wind, and I am afraid he was almost inclined to find fault with Providence because it had not created a wind just when poor little Sam wanted to have it blow. Sam's mother remonstrated with him, and endeavored to tell him that he must learn to be patient, and not to find fault with the weather. She explained to him how he was finding fault with God.

Just before Jimmy left that evening, he suggested to Sam that they attach a bell to the shaft of the windmill in such a way that, when the latter started to run, the bell would tingle. No sooner was this suggested than the boys put the idea into execution; so just before Sam went to bed he stepped out into the back yard again, and listened and listened in vain for the tingle, tingle, tingle. After he went to bed his mind was full of windmills, and, with his thoughts thus occupied, he went to sleep. As all boys are apt to do when their attention is centered on one object, just after going to sleep Sam began to dream, and he thought he was waiting for the wind to blow, when all at once it seemed to him he heard the tingle, tingle, tingle. The note was so musical to him that it wakened him suddenly from his sleep. With a bound he struck the floor, stuck his head out of the window, and listened; but "nary a tingle" was heard on that calm clear night. He heard the croaking of the frogs (for the night was warm), and peered anxiously over

toward the barn. But the windmill stood still like a ghost, apparently mocking him. He looked at the moon, and imagined that he saw a broad grin on her round full face. "Only a dream," Sam muttered to himself, and with this he proceeded to his bed.

The next thing Sam knew he was awakened by the crowing of his big Brahma rooster; and as he raised himself in bed, he saw that the gray light of morning was creeping in at his window. Of course, Sam got up and looked toward the barn; but no wind and no tingle. "Did you ever!" said Sam to himself. He hurriedly dressed himself and went down. As he came out into the back yard, Jimmy breathlessly greeted him, and asked him if he had heard any tingle during the night.

"No," said Sam grumblingly.

"Well, there is just a little wee mite of breeze, anyhow," replied Jimmy, inclined to take courage.

"Well, I can't feel it," said Sam, in a tone that indicated that he didn't believe the wind would *ever* blow.

Sam felt irritable, and, to make matters worse, his sister Mary felt in an uncommonly good mood for teasing him at breakfast that morning.

"You can't make your windmill go," said Mary.

"I could if there were wind," retorted her brother.

"Never mind, dear Sam; just go and get a couple of old smokers and blow on your windmill."

"Ma, make her stop," said Sam indignantly; "she is all the while a teasing and bothering me."

Sam's face began to pucker up for a bawl, whereat even Mrs. Green could hardly refrain from laughing, to say nothing of Mary. A hot tear trickled down Sam's cheek, and he inwardly resolved that the windmill *would* go. His father consoled him somewhat, saying that when he came in he noticed a little breeze blowing from the west, and he felt quite sure there would be sufficient wind by noon.

Jimmy and Sam started for school. At recess, a crowd of boys gathered around the two famous windmill-builders.

"Your windmill didn't go, did it? I knew it wouldn't, and I told you so last night," said Jake. "I'll bet you five dollars you will never be able to make it go," he continued.

"Humph!" said Sam, "you never had a cent in your life, and you haven't gumption enough to whittle out a paddle to kill bumble-bees with."

One or two sided with Jake; but the most of the boys were greatly interested in the enterprise. There was more or less talking kept up between the two factions, until quite a heated discussion grew up as to whether that windmill would run or not. Jim was just on the point of "licking the stuffing out of Jake," or "teaching him a lesson or two to make him mind his own business," when the school-bell rang for the close of the recess. Although the crowd of boys had just begun to yell "fight!" "fight!" in anticipation of some fun, they dispersed.

After school was out, the two boys noticed that there certainly was quite a breeze; and if the windmill would run at all it would run then. They both started on a double-quick trot for the scene of the windmill, followed by a number of the boys. When they reached the street, Ted met them with the joyful intelligence that the "wheel was goin' round and round like every thing." Sam and Jimmy cast one satisfied look at Jake. The latter did not appear to enjoy the news very much. When the boys reached home, sure enough the thing was "going like split," as Jimmy expressed it. The joy of the two boys knew no bounds, and all the fellows seemed to share with them in their pleasure, save Jake and one or two of his companions, who were starting down street by themselves. Jake was mad to think "that silly cur Jim had threatened to 'lick' him," but "he would show him whether he could or not, when he got him alone." Jimmy, however, now that the windmill was running, felt no ill will toward anybody.

The two proprietors of the bee-hive factory had as yet rigged up no saw-table, nor had they even ordered a mandrel; but as they desired to test the power of their windmill they lugged Mr. Green's grindstone up the flight of stairs into the barn loft. They had no belting, so they used common clothes-line instead. Just as the boys were about to connect the grindstone to the windmill, Sam's mother called out that the last bell for the afternoon school was ringing, and that they must both hurry. Sam begged piteously that he might be allowed to stay out, and Jimmy said that his mother wouldn't care anyhow; but Mrs. Green insisted that both the boys had better go to school; and when they came home in the evening they would enjoy their experiments so much the better. With reluctance they obeyed.

To be continued May 15th.

JUVENILE LETTER-BOX.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

A MULE STUNG TO DEATH.

I write to let you know about an accident that happened the other day. A pair of mules ran away, and ran to a house close by. The bees were in the yard. The mules ran over a bee-hive, and the bees stung one of the mules to death, and the other nearly so. Our bees are doing finely; but if it does not rain soon they will not do much.

THOMAS E. WILLIS, age 10.

Jonah, Williamson Co., Tex., Mar. 26, 1887.

Thanks, friend Thomas. This time it was a poor mule that was the object of the bees' wrath.

POLLEN FROM CEDAR AND HAZEL.

My pa has 85 colonies now; 25 died last winter. They are all doing well this spring. They began carrying in pollen about two weeks ago from cedar and hazel. The pollen is red which they get from cedar, and yellow from hazel. Pa says it is

the first time he ever heard of bees gathering pollen from cedar. I have one swarm of bees. Pa has put in about 1500 grafts this spring. He is thinking of going into the nursery and bee business together. We have had a very rainy spring so far, and the bees have not had much time to work. We have some very fine Brown Leghorn hens.

HOWARD ALLEN.

Snohomish, Wash. Ter.

REVIVING FROZEN OR CHILLED BEES; SAW-TABLES.

Winter before last we had a colony freeze, and in three or four days the sun shone warm and we got a handful of them and put them in the sun; they came to life, and we gave them some honey. They ate it, and flew away. This proves that bees will sometimes come to life after being frozen. We have 15 hives of bees. We take GLEANINGS, and think there is no better paper. Our country is not the best for bees. The honey-crop is uncertain. We bought a hive from you in 1883, but have since made a horse-power saw and make our hives. I notice in GLEANINGS for Feb. 15, 1887, an improvement on saws, and I think there would be a still greater improvement if Mr. Warner would attach the same device to raise and lower his table.

WM. C. GREER, age 13.

Paris, Tenn., Mar. 20, 1887.

Thanks for the experiments you give in regard to bees supposed to have been frozen. Some experiments were given in our back volumes, I believe by friend Doolittle, where bees, exposed to a temperature below the freezing-point for 24 hours, could be revived by warmth and then feeding; but he found that where they were kept frozen for 48 hours, they were past recovery. This same matter is touched upon in the A B C book, under the head of "Wintering." In sending out queens during the early spring months, we have to tell our customers that, should the bees arrive at their destination apparently dead, they are to place them in a warm place and allow them to remain for a few hours. Where they have been chilled, or even frozen, in this way for a few hours, they will soon revive by the application of warmth. About the first of last January we received a queen from Nellie Adams, Sorrento, Fla. The queen clerk thought that the queen and her bees were surely dead. They were, however, placed over one of the steam-pipes, and in the course of two hours they were "alive and kicking."—It is true. Warner's chain and screw attachment could be fastened to the table in such away as to raise it, but Mr. W. says it would be no advantage. Screws for raising the table were used years ago, but I believe now are generally discarded, both because they were too slow to operate and because they would not hold the table rigid enough. The device we have for raising and lowering the table is much better, we think, for hive work than any thing else. It can be quickly raised and lowered, and can be clamped securely so as not to jar or move. In making hives it is very important that all parts of the saw-table should be strong and rigid. Well, friend Willie, we think we shall have to send you a panel chromo. These little facts are just what we are after.

FEEDING CHEAP SUGAR.

My papa has about 20 stands of bees living. It is a good idea to feed bees New-Orleans sugar in the winter, to keep them alive. Papa claims you as a friend of his.

STELLA JENKINS.

Smithville, Mo.

BEES GATHERING HONEY IN ILLINOIS BY THE 14TH OF MARCH.

Pa has 23 swarms of bees. They are all working strong, and have made some honey for a couple of weeks. This is the earliest they have ever gathered honey. Pa thinks they are working on maple. Our bees are hybrids, and are very cross. Ma has been stung three times, but it didn't amount to much.

JOSIE NEFF, age 12.

Lewistown, Ill., Mar. 14, 1887.

A CHEAP BEE-VEIL.

I live near Bradford, White Co., Ark. My pa takes GLEANINGS, and I like it very well, especially the children's page. This spring we started with two swarms, and increased them to 12 strong colonies. To make a cheap bee-veil, take mosquito-bar and cut a piece long enough to go over your head with your hat on, and draw it tightly around your neck, and the bees can't sting you.

ALBERT REMLEY, age 14.

Bradford, White Co., Ark.

BEES AND CARP.

Pa has 51 colonies of bees. They are all in the cellar. We have a carp-pond, and we found two large dead carp frozen in the ice, after our thaw in January. Pa says he is afraid they are all dead.

Constantine, Mich. EDNA RIFENBERGH, age 11.

Tell your pa not to borrow trouble, friend Edna. We find more or less dead fish on the surface of the pond every spring; but when we commence feeding them we find there are enough left to make things lively. I do not know why they die this way, unless it is because the water is too shallow. We have arranged to make our pond quite a little deeper hereafter.

KEEPING HONEY FROM CANDYING.

Pa has been keeping bees for four years. He has 23 colonies in good condition. If they pull through all right they will make things lively here about swarming time. We have never had a pound of candied honey in our house since we kept bees. Mamma believes if honey is put into jars or cans and kept in the third or fourth story of a building it will remain in a liquid state the whole year round. Mamma would like to know how to make honey-jumbles.

JOSIE NEFF, age 12.

Lewistown, Ill.

Tell your mamma, Josie, that we think it makes more difference as to whether she seals up the jars or cans as we do canned fruit, than whether she puts it in the third or fourth story.—I am sorry to say the manufacturers will not give us the recipe for making honey-jumbles. They are made at a very large factory.

HOW RAY MAKES MONEY.

I made half a dollar from papa. He told me he would give me five cents for every swarm I saw. He saw a swarm of bees, and he went up and hid among the bee-hives. I saw it too, and I went up and screamed and hallooed a long time, and Hattie told me that pa was up there, and he pulled out

half a dollar, and five cents. He told me to take my choice, and I took the half-dollar and put it into my bank. Mamma has a great lot of chickens, and every time she goes to feed them she talks to them.

Waynesburg, Pa.

RAY INGRAM.

Friend Ray. I do not believe I would say that you *earned* half a dollar in the way you mention, but, rather, that your papa *gave* it to you, and I presume he knew by past experience that so good a boy as Ray would make a good use of it, and he therefore considered it a safe thing to do. How is it, Ray? Didn't I hit it about right?

A REPORT BY A LITTLE GIRL.

We have kept bees for about 35 years, but never gave the business any special attention except for the last ten or twelve years, producing but little honey more than for our own table. Lately the number of colonies has been increased; and last spring, at the commencement of the honey season, we had 140 colonies.

We have two bee-houses; one is 11 x 52, and the other is 11 x 24 feet. Both are built mostly under ground. One is built of stone, and the other of timber. The bees winter nicely in either of these houses. We have now 212 colonies, and papa said they were in fine condition. We work exclusively for comb honey. The yield of honey last year was small, being only 9000 lbs., but this is easily accounted for from the fact that more than half of the bees died during August and September of the previous year, leaving them very weak in the spring.

We use the Langstroth hives. Our bees are blacks, hybrids, and one colony of Italians—mostly hybrids.

LOU MAY RANDALL, age 11.

Big Rock, Ia., Feb. 10, 1887.

HONEY FROM THE COTTON-PLANT; THE ITALIANS GATHERING WHEN THE BLACKS ARE DOING NOTHING; THAT NEW KITE.

Papa's bees came through the winter all right. They have been bringing in pollen more than a month. They are gathering some honey now from peach-bloom and willow. Last spring was a failure in honey. The late freezes killed all the flowers. Papa's bees are part Italians and part blacks. When the cotton bloomed, the Italians made enough for their own living, and some to spare, while the blacks made nothing.

Brother Clay's kite that he got from you was a perfect success. Papa put some strips of paper on the middle corners, to imitate wings. They add to its beauty a great deal. It flies over 200 feet. Clay takes pieces of paper, makes a hole in the center, puts them on the string at his hand when the kite is up. They will run up to the kite. The kite dives and looks like a hawk after a bird. Tell Caddy and Blue Eyes that I make a house-vine with a sweet-potato put in a small bucket or can, partly filled with water. All I have to do is to keep water in the can and train the vine as it grows. It grows very fast after it gets a start. I can't get one to make a long vine after the potato has been bedded out. Can any one tell me why? Keep them inside the house. Put a little bat of cotton in a glass of water, sprinkle oats thick on it. They will grow and make a pretty sight. Mamma has that vinegar-plant you ask about on page 212. You describe it exactly.

MATTIE F. DILLEHAY, age 12.

Wilford, Texas, March 24, 1887.

TOBACCO COLUMN.

THE VALUE OF THE TOBACCO COLUMN.

I HAVE just got through running back over the Tobacco Column, and footing up the number of persons who have, by the good influence of GLEANINGS, quit the tobacco habit. I had two objects in view in footing up the list: 1. I wished to use the item in some of my public discourses, to show what is being done by one man to induce his fellow-men to discontinue a much worse than useless habit; 2. I wanted you to know that your "labor was not in vain." I counted only those who indicated plainly that it was through the influence of GLEANINGS that they had quit it. Here is the list, if I have made no mistake, and I think I am right:

Whole number quit—446. Number who had quit, but broke the pledge—18.

Is not that encouraging? Just think! What a little army of men—enough to fill a large hall! A large number of those reformed, I noticed, had families; and I verily believe that, through those fathers, we can count at least on 446 boys belonging to them that will be led on to manhood without acquiring the pernicious habit. Quite a number testified that they had used the weed from 40 to 60 years. I think we may all wish the good work a hearty God-speed, and that still many more may yet be induced to join the anti-tobacco army through your efforts.

D. E. BRUBAKER.

Maxwell, Story Co., Ia., Mar. 7, 1887.

We are very much obliged to you, friend B., for the pains you have taken to count up the number who have given up tobacco, and I agree with you that this number does not probably represent all the good that has been done. A great many have given up tobacco just because of these letters, and have never said a word about it. A good many whom I have met at conventions have told me as much. The idea of giving a smoker seems to have struck the matter in a pleasant way, and people have been stirred up to a sense of duty by it, without feeling as if they had been either reproached or censured.

TOBACCO A YOUNGER BROTHER OF ALCOHOL.

I am glad you still hold on to the Tobacco Column. Undoubtedly you are doing untold good that eternity alone can reveal. I believe tobacco is doing about as much harm in this world as alcohol. About \$900,000,000 spent for alcohol in the United States, yet its use is not so popular as tobacco. Why is it that almost every person who drinks, first used tobacco in some form? Physicians say it is because tobacco creates a desire for stimulants. About \$600,000,000 spent yearly in this Christian country for tobacco, and but \$5,500,000 for both home and foreign missions. Does this look consistent for a Christian nation? What answer will the Church make to God—what shall we individually make, when asked, "Where is thy heathen brother?"—856,000,000 who have never yet heard of Jesus? Do not our small givings to send them the gospel look as if we answered, "Am I my brother's keeper?" And will God hold us guiltless? Nay, verily; in that we have slighted our Savior's last command, to go into all the world and preach the gospel to every creature.

Many say, it is so hard to leave off tobacco. That is the reason they do not give it up. But there have three cases come under my observation within the last two years, of old men who have used it for 20 to 25 years, leaving it off when they found it was killing them. One of those men found he could not do it in his own strength, and took it to God in prayer. He claims the appetite was entirely taken away. On another, three cancers started on his head and face. The doctor said it was from the use of tobacco, and said it could not be cured unless he left it off, which he did immediately. The third one is improving in health. If old men can quit its use after using it so long, why can not any one who has a will to? The reason most people use it is, they do not think it really bad, and young men and boys think it manly because their seniors use it.

Roseville, Ill.

MRS. L. C. AXTELL.

A FRIENDLY LETTER FROM ONE WHO HAS USED TOBACCO 46 YEARS.

I am a beginner in bee culture. A year ago I bought a hive of Italians of Rev. Mr. Whitehill, of Cuba, and got a fine swarm from them. Last fall I found and secured in good condition a wild and very strong swarm of black fellows, so now I have three. Rev. Mr. Whitehill kindly loaned me his copy of the A B C of 1882, and I find it a necessity next to bees themselves in bee-management. I write to inquire if you have a later and revised edition. If so, I wish to procure for the elder the improved and take his old copy. It is good enough for me, and I guess he has read about all of the sense out of the old copy. A lady friend handed me a copy of GLEANINGS. I like the tone of it very much. Your Tobacco Column seems to me a novelty. Now, if you wish to risk a Clark smoker on an old tobacco-smoker like me, who has indulged the habit 46 years, send it on, and I will accept your terms. If I don't quit smoking I will pay for the smoker; and if I do quit, and know that I have effectually and for ever quit, I will also pay for the smoker.

W. D. STEWART.

Cuba, Mo., Feb. 14, 1887.

Well, friend S., you are the first brother, I believe, who insisted on paying for the smoker, no matter what the result might be. You pay for it if you quit smoking, and you also pay for it if you don't quit smoking. I am to be the gainer, in either case. Come to think of it, however, I believe, dear brother, you will be the gainer also, if you think you will use less tobacco than you did before, and my faith is *pretty strong* that you will never use it at all any more.

A USER FOR 33 YEARS OUT OF 40.

Please send a smoker to your humble servant. I have quit the use of tobacco, having used it 33 years out of 40. If I ever resume the use of tobacco I will pay you for the smoker. This is something I don't like to say. I am not trying to quit, but I have quit.

T. R. DELONG.

Oxbow, Neb., Mar. 4, 1887.

Mr. Dock Connon, of Madisonville, tells me you gave him a smoker to quit the use of tobacco. As I am handling bees on a small scale, I need a smoker. If you will send me one I will quit the use of tobacco; and should I fail to keep my promise I will send you the money for the smoker.

Middleton, Tex., Feb. 6, 1887.

L. S. WILMER.

I have quit the use of tobacco; if I use any more I will pay you for the smoker. J. E. CLARK.
Hartville, Ga.

I have quit using tobacco. If I ever use it any more I will pay you for the smoker you send.
Hartwell, Ga., Feb. 25, 1887. C. C. WHITE, JR.

Please send Henry Stevens a smoker. He quit using tobacco over a year ago, and proposes never to use it again. If he does, I will pay for it.
Belle Rive, Ills., Mar. 7, 1887. D. B. COX.

I will give up the use of tobacco; and if you send me a smoker, and I should break my promise, I will send you the money for the smoker. J. SAMS.
Postville, Ia., March 2, 1887.

I am resolved to quit the use of tobacco, if you will send me a smoker; and if I ever use the weed again I agree to send you full value for the smoker. HAM GREEN.
Fayette Corner, Tenn., Feb. 21, 1887.

I have stopped chewing tobacco, and will promise you never to do so again. If you will send me one of your smokers, and I commence using the weed again, I will send you price of it. G. W. HICKS.
Milan, Tenn., Mar. 8, 1887.

HEALTH IMPROVED.

I have quit chewing tobacco after using it about 25 years, and I feel better. I think it did me a great deal of harm, so I make the usual promise, if you send me a smoker. GEO. W. WHITNEY.
Bettsville, O., Mar. 1, 1887.

WILL KEEP THE PLEDGE.

I promise never to use tobacco any more. If I do, I will send you 70 cts. for the smoker. If you see fit to send me the smoker I shall be pleased, and will keep my pledge. B. FREDERICK.
Jerry City, O., Feb. 26, 1887.

INFLUENCE OF A FRIEND.

Will you please send a smoker to Silas Mitchell, of Jordan, Ky.? He has recently quit the use of tobacco, and says if he ever uses it again he will pay the usual price for smoker. I vouch for him. W. B. CLOYES.
Jordan, Ky., Mar. 9, 1887.

NEVER TO USE IT AGAIN.

I have stopped using tobacco, and will promise you never to use it again. If you will send me one of your smokers, and I commence using tobacco again, I will pay you for the smoker. J. H. POUNDS.
Milan, Tenn., Mar. 6, 1887.

NEEDS A SMOKER.

I will abstain from the use of tobacco. I have just bought some Italian bees, and need a smoker. If you will send one I will agree to pay the price you ask. F. J. BUSER.
Glenn's Valley, Ind., Feb. 26, 1887.

A BARGIAN THAT IS BINDING.

I am a young beginner with bees. I have always used the pipe or cigar, but I have become disgusted with tobacco, and it is likewise such a bad and mean habit that I shall never use it again under any circumstances. If you think I am entitled to a smoker, send me one; and if I ever catch myself using the weed again I will pay you one dollar for it; besides, one hundred dollars more to any one charitable institution you may name. G. O. SALZMANN.
Harmer, O., Feb. 22, 1887.

FIRMLY RESOLVED.

I have been chewing tobacco for a long time, and quit some time ago. I have now firmly resolved never to use the weed again. If you think me entitled to a smoker, please send it; and if I ever take up the habit again in any way I will pay you for the smoker. JACOB HOPPLE.
Cocolamus, Pa., Feb. 22, 1887.

A LITTLE GIRL'S INFLUENCE.

My pa began to read GLEANINGS last spring. He has the A B C, and likes it real well. He has 50 stands of bees. He has quit the use of tobacco; and if you will send me a smoker I will see that you get your pay for it if he ever commences again. LIZZIE BILES.
Homet's Ferry, Brad. Co., Penn., Mar. 3, 1887.

"A USELESS AND EXPENSIVE HABIT."

I never used tobacco except in smoking, and I quit that last fall—not because of your offer, but because I considered it a useless and expensive habit, totally devoid of any good whatever. Now, you can suit yourself about sending the smoker. W. J. CULLIMAN.
Mt. Sterling, Ill., Jan. 21, 1887.

THE TOBACCO QUESTION.

You give a smoker to all who quit, and promise to hold out faithful, which is very good. I have been trying to educate my boy to never commence the vulgar practice. So far he has obeyed both me and my better half. He is now nearly fifteen years old. His name is Curtis W. He goes to school the most of his time, and studies all the common branches. Also my better half's brother's boy, Medford Whistler, a few months younger than Curtis. He has yet not commenced using tobacco in any way. I think if any are entitled to a gift it is the young men or boys who never chew or smoke. I will say, if you think these boys worthy of a smoker, send them one apiece; and if they commence, then you will get your pay for them. I will now let Curtis write a few lines. H. D. BRUBAKER.

I never expect to use tobacco. We have one stock of Italian bees, which we put into winter quarters last fall. When should upward ventilation be stopped? Should it not be done now? Father attends to nearly all the bees in this vicinity. CURTIS W. BRUBAKER.

Irvin, Ind., Mar. 7, 1887.

I am much obliged for your kind letters; but if we offer a smoker to every one who does not use tobacco, it would be virtually offering them broadcast to almost every one. Now, I am not afraid to give away this vast sum of money if it would be productive of good; but the probabilities are that it would not, or, at least, not very much. As it is now, the smokers we give to tobacco-users are given as a sort of pledge. If they use it any more, they pay for the smoker. Tell the boys that Uncle Amos appreciates their good behavior, and is glad to know that they have been so well brought up. If they go on in the way they are going, they will save money enough to pay for a great many smokers, besides having good health and a clear conscience.—Upward ventilation should be mostly stopped now, though it depends upon the weather.

OUR HOMES.

If thine enemy hunger, feed him; if he thirst, give him drink.—ROM. 12: 20.

I DO not know, my friends, but that I shall put a little different construction upon this verse from the one usually given to it; or, rather, may be I shall start off on a different line of thought. Missionaries have long since decided that the first thing to be done toward winning souls is to *feed* the heathen, or win their confidence and friendship by giving them something pleasant to the taste and satisfying to their hunger. And it is not only the heathen who are won by something good to eat, but it is the street Arab of our cities; and, in fact, the bad boys of our towns and villages may often be won from evil ways by something pleasant to the taste or satisfying to their hunger. Somebody has said that the shortest cut to a man's heart is down his throat, or something to that effect; meaning that, if he is to be won to better things, or to good nature, if you choose, the quickest way to do it is to give him a good palatable square meal; and, indeed, I have discovered that the same law runs through all the animal kingdom. If you want to win the confidence and affection of your horse, give him choice morsels whenever you come around him—a little salt, a little sugar, or an apple; in fact, almost the only method of leading animals to go where you want them to go is by rewarding them with something they love to eat. My Brahma chickens I have so often told you about have feed and drink right where they have constant access to it; and I have discovered that this state of affairs is a constant bar to close acquaintance. They do not care to be handled or meddled with so long as the grain-hopper and the water-fountain never need replenishing. Let one or the other give out, however, so that the chickens get hungry or thirsty, and they will walk right up to me, let me pick them up, or do what I please with them, especially if they can remember sundry handfuls of corn given them at such times, or a panful of nice clean water when the water-works happen to be temporarily suspended. How I do love to see them enjoy their food! I also love to see them enjoy nice clean pure water. Somebody has said in sarcasm, that, when the chickens lift their heads toward the sky, and wink their eyes as they let the delicious cooling draught go down their throats, they do it in praise to the great Creator of all things. No doubt they feel thankful when fed, and supplied with nice water; but I am unable to say whether their little brains can compass a thought so great as to include the Author of their being or not.

I wonder if you begin to suspect that I am going to talk about food and drink this time. Well, that is to be one of the principal objects of my talk. The Master said, "Do good to them that hate you;" and as if somebody might have asked the question, "How shall we do good?" Paul placed first and foremost, food and drink. Many

of our young people in prayer-meetings, and in conversation with their pastor or other spiritual advisers, say, "How can I do good to anybody?" May be you, my young friend, who have sometimes felt a burning desire to follow in Christ's footsteps, have asked yourself the question, "How shall I do good to anybody?" I answer, "In the line of food and drink." If you want to win your papa to Christ, and wish that he may love the Savior, study his wants and tastes, and assist mamma in providing promptly something nice for him to eat, or a cool refreshing drink when he is too tired to go after it himself.

Now, skipping by these domestic relations and taking the world at large, whenever the question comes up, "How shall I win souls to Christ? or, how shall I show to God that I love his creatures and my fellow-men?" my answer is, "Through the medium of food and drink." Some way it has seemed to me that the world is careless and negligent, and I have sometimes thought actually selfish, in this matter of food and drink. We pay big prices for a meal of victuals; yes, it seems to me prices far beyond what we pay for other comforts proportionally. No one, I believe, thinks of furnishing a meal of victuals to the traveling public for less than 25 cts.; and even in a country town, if you get a meal that is decent and nice, the price is 40 or 50 cts. In towns a little larger, it is 50 or 75 cts.; and in our cities it comes up to 75 cts. or \$1.00; and I am told that even \$1.50 for a single meal is sometimes asked, but I have never in my life paid over a dollar. Those who receive money for feeding the public, should, of course, render a fair equivalent for the amount of money received; but, my friends, there is something that humanity is hungering and thirsting for, that money can not buy. It is friendly and home-like service. It is the kind of service that the mother gives to her children because she loves them. One of our great workers among the lost ones in our cities once said, "Never give any thing to any one, without breathing a prayer that God may bless the gift;" and I think it should be so when one who loves the Savior furnishes or assists in any way in providing food for the hungry multitudes. Jesus set us an example when he passed the bread to his disciples. It was his custom to bless it and give thanks.

Sometimes good may be done by making a gift of food. Drinking-water is always a gift, so far as I know. In fact, I have never heard of any one charging for it, and I am sure that great good has already been done by the Women's Christian Temperance Union, and other benevolent societies, in providing ways and means to furnish refreshing water wherever hungry and thirsty mankind may be expected to long for it. How I do love neat and tasty drinking-fountains and bright clean bubbling springs! Why, I have often felt that I would go miles just to look at one, and I am glad to notice that Blue Eyes is just beginning to share her papa's enthusiasm in the matter of springs of water. I remember one about twelve miles from my home that gushes out from the rocks near the summit of a very long

high hill. I would to-day give \$1000 cash down for such a spring as that, at the Home of the Honey-Bees. Of course, I would make use of the water for other purposes than for drink. My friend, do you know of anybody this moment who is thirsty? Is there any one who would thank you for a drink of cool water? I do not mean that you should take a dipper and carry it to them just at this moment, but that you should provide a permanent drinking-place that will perhaps refresh the passerby, not to-day only, but generations to come, as well. You want to serve Christ, and you do not know how. Serve him by paying five cents for a bright new tin cup, and then put that cup where it will be used. If it gets battered up, or is lost or stolen, rejoice that it is being used, and then put another in its place. When the Master said, "Whosoever shall give to drink unto one of these little ones a cup of cold water only, in the name of a disciple, verily I say unto you, he shall in no wise lose his reward," I believe the thought included furnishing drinking-water to the thirsty in just the way I have indicated. A great many times, fresh water placed on the table at meal time will make those who gather round the family board feel happy and grateful. I have often heard my father say, when asked whether he would take tea or coffee, that he would much rather have a glass of fresh water. It used to be my office to bring water from the spring, in a little pail. Dear young friends, how many dollars do you suppose I would give to have the privilege of bringing my old father a drink of cool water this bright warm spring day? Do you ask why I talk about things which are no more possible in this world? Because it is possible for me to give a drink of water, even now, to somebody's else father, and it is quite likely that you, my readers, can have this privilege, right this minute, of making your dear old father look happy and thankful by carrying him a cool refreshing drink now; and Christ has said, "Inasmuch as ye did it unto the least of one of these my brethren, ye have done it unto me."

Do you suggest that I am talking about giving food and drink to friends instead of enemies? Why, my friends, if these kind offices were performed oftener to friends, they would remain friends and not change to enemies. I have known of people to feel quite hard, and may be bitter, toward those who should have been their friends, because of carelessness in this respect. A tired man sits down to a meal, and, through carelessness or indifference, perhaps he is not waited on as he should be. He lets Satan whisper to him that his family do not care for him; that they are all selfish, and bent on their own comfort. May be by and by he says something ill-natured because of this neglect, and enmity springs up in the family circle. I suppose that not many of us have what might really be called enemies; and may God grant that there are no *real* enemies under the roof that covers what we call home; but for all that, I do know there are hard, uncharitable, and unkind feelings, many times, cherished by the inmates of

these our homes. The Bible says we are to feed an enemy; how much more, then, should we feed a friend or one related to us by the ties of kindred!

I do not believe that, as a rule, it is the thing to do to furnish *food* without equivalent. I do not believe in giving that tramp who stops at our doors, pie and cake. In fact, I think it will harm him rather than do him good, because it would encourage him in a sort of dependence that is exactly the opposite of manliness; but when we receive *pay* for any thing in the line of food, I do think it behooves us to try to honor the Master by giving good measure, good quality, and have it in nice and attractive shape, as the market-gardeners and fruit-growers tell us so much about. A great part of the business of our every-day lives is in buying and selling something concerning food and drink. If it is your business to wait on the table, say to yourself constantly, over and over, that in ministering to the wants of those who are looking to you, you are serving the Master. Not only see to the food, but provide your guest with clean water and a neat tidy wash-basin, and a refreshing-looking napkin, that he may bathe his hands and face, as a preparation toward the full enjoyment of his meal. This last remark hits me right squarely; for since our lunch-room has been prospered until now it is crowded almost every day to its full capacity, we have never yet arranged a convenient place for the traveling public to wash, without going upstairs. Of late years I have traveled quite a little, and one of my enjoyments in traveling is to see how much this matter of the comfort of the traveling public is made a study—or, if you choose, I like to notice how much Christianity there is about the hotel-keepers, the girls who wait upon the table, and others who serve at such a place. The waiters at our hotels are a class that is on my mind a good deal of late. One of the bee-friends made the remark at Albany, N. Y., that it was ever so much pleasanter to him to be waited on by women than by colored men. At the large hotel in Indianapolis they had, as a matter of course, colored waiters. We were kept waiting for from fifteen to twenty minutes for our meals, after giving our orders, when some one at the table suggested to one of these colored waiters that he had business that was hurrying him. The only reply he got from the waiter was, "Well, I guess you will wait till you get it." Another colored waiter did not bring the ice cream I ordered, and I suggested to him his delinquency. His reply was that he could not remember who ordered it, and so *he ate it himself!* Now, such things are unpleasant. Of course, one might complain at the desk, and, in fact, a card was appended to the bill of fare, *asking* guests to do so, from which I inferred that there was often need of it. At this place we paid the highest prices, and had a right to expect kind and civil treatment. Do you want to know what kind of waiters I like? My friend, it is Christian women. I do not know how many Christians can be found at our hotels and restaurants as waiters, but I do feel as if it

would be a privilege to me to help to pay Christian men a big price for such services, and then I would have some measures taken to demand that these waiters bestow Christian treatment and Christian courtesy; this latter point might be a hard matter, but I think I see indications already that it is coming. I notice it in the daily papers, and I notice it in the daily talk. In the near future, I think the cause of Christ is going to be magnified, and his name is going to be glorified. I know it is a fact, that women-waiters in many public places are obliged to hear things that are unpleasant, and many times they are censured when they are not at all to blame. Sometimes they are bantered; but I think a wise and discreet woman can, as a rule, by her bearing, pretty quickly check or discourage any of this latter. I have wondered many times how many of these women are in the habit of attending weekly prayer-meetings. Do their employers so arrange their work that they are permitted to go? and when they have guests who are hard to please, do they have the cheering influences of Christ's presence in their hearts, to help them bear the trials of every-day life? Is it possible that, among the readers of GLEANINGS, there is one who waits on the table, for the great traveling public? If so, may God's blessing rest on such a one; and may she realize how much it is in her power to work for the Master, perhaps not directly by serving her enemies, but she surely will have opportunities, almost daily, of feeding those who are enemies of the Savior; and shall we not consider *this* a great privilege?

"For inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me." The matter of food and drink contributes more toward making people feel pleasant and happy and Christianlike, than we perhaps realize. One may feel tired and faint and cross; but the sight of tempting food, tastily arranged, is one of the great aids in helping to put away bad feelings, and make one to feel pleasant; and when added to this we have pleasant and courteous treatment, it is a wonderful help toward good feeling and gentle bearing. On the other hand, when one feels tired and faint and cross, how much more apt he is to indulge in unkind words if the food is not as it should be, and the dining-table in disorder! I need not enumerate these things, for they have been seen by almost every one too often. Sometimes the waiters are busy with something else; and after pushing the bread, and the cream and sugar, and perhaps meat and potatoes, toward the hungry one, they turn off to something else. May be the bread is forgotten; perhaps the coffee is forgotten. Of course, one is at liberty to speak out when what is justly his due is not given him; but one who is faint and hungry is not likely to have an extra amount of Christian graces just at that precise moment. In fact, I have sometimes thought that Satan made haste to make the most of such an occasion. He whispers to the hungry one, "The world is hollow and selfish—the whole of it; there is no such thing as get-

ting your just dues anywhere without fighting or making a fuss about it." Who knows but that some poor soul might have been saved from crime, perhaps suicide, by a little more care in this one thing of food and drink—loving care from those on whom the responsibility falls, of looking after these little matters of food and drink?

If thine enemy hunger, feed him; if he thirst, give him drink.

Are not these wonderful words? Paul did not mean that you were to feed your enemy grudgingly, but as if you loved him, and were anxious to win him back to friendship. Feed him as if you enjoyed doing it, and you soon *will* enjoy it. Years ago, before a loving wife looked after my wants in the way of food and drink, I can remember once or twice of being served with short rations just because I could not consistently avoid offending those who had it in their power to minister to my wants with a slack or lavish hand. I could not well help myself just then, and so I bore it; but what a miserable way to vent your spite on any human being, by obliging him to go hungry!

By the way, dear friends, did you ever think how extremely natural it is to pay back, or render evil for evil, to any one who has misused you or wounded your feelings? Where is the man or even woman who feels like doing kind offices in repay for unkind ones? Human nature is all against it. I have talked about rendering good for evil, and doing good to those who hate you, for nearly a score of years. I have told you how it rejoices my heart, when opportunity presents, of heaping coals of fire on the head of an enemy; and now, after all I have said and done in this line, my first impulse is almost always, even now, to strike back. Even while writing this paper to you I was interrupted, and called out of the room. Something was going wrong—something that needed my immediate attention—something that needed stopping at once. The power lay all in my own hands, so I had but to say the word, and the friend who had offended would be made to suffer. Now, I do not know but that I should have said that word had I not remembered how many, many times I had resolved that I would go slow at such times, and first see whether my course were exactly in the line of Bible teachings. It is human to return evil for evil, but it is divine to render *good* for evil. I am glad that Paul made the suggestion we have in our text, for it seems to be the easiest and quickest way in the world of doing good to anybody, to watch for an opportunity of ministering to his hunger, or of giving him drink when he is thirsty.

My friends, it is not unlikely that you can put this admonition in practice within the next fifteen minutes after you read this paper. When I was a boy I used to be cross and peevish and fretful, a great many times. Next to me in age was a younger sister, and, by the way, I have a picture of that sister now. I can look on it and see exactly how she used to look when I was a dozen years old, and she was was, may be, two years younger. I was not a very good brother;

but she was a wonderfully good and kind sister. If, during my absence, there was any fruit brought into the family—any sweetmeats, or any thing that she knew I liked, she would always save some of it for me. Perhaps grandmother would bring us some maple sugar; and if no one else would remember the absent brother, this sister did; and it did not make any difference whether I was unkind or not, she was just as ready to do me kind services. A great many times she made me feel ashamed of myself by her mild, gentle ways when I was overbearing and rough. God bless the sisters of our land! I wonder if they know how much it is in their power to win wayward brothers to better things. And this matter of food and drink comes right in here: it is their province—their privilege. Now, I do not mean to be altogether one-sided, dear friends. I know the troop of brothers in our broad land have it in their power also to do the same thing for these sisters in the way of food and drink. They can help the sisters to find the wherewith for this same food and drink we all must have. We can win each other—do you see? And when we get really about it in the home circle, we shall very soon feel like extending these kind offices to the neighbors over the garden fence or across the way. In our bee-conventions we have heard over and over again how some irritated neighbor had been softened by a simple section of honey—something for the evening meal, and to please the little ones. Now, my friends, it is not about bees alone that neighbors quarrel. Hard feelings come up about the chickens, and sometimes about the cows and pigs as well; again about the line fences; then about borrowing, and in all kinds of business deal. Have you a mean neighbor? Good people as well as bad people are evenly distributed all over the land, and most of us have had experience with both kinds. Now, then, if you have a mean neighbor, of course you want to cure him, and you want to make him decent and pleasant to deal with; you want to make him fair and honest, neighborly, and progressive. How shall we go about it to secure this end? Why, there is no better recipe in the world than the one Paul gave. Wait until he is hungry, then send over something appetizing. If you can not manage it in a neighborly sort of way, ask your wife to help you. Women have a wonderful tact in this kind of thing. Get acquainted, anyway. I do not believe it is right to have neighbors, and not get acquainted with them. Some people will say of certain ones, "The less you have to do with them the better." I do not believe it. I am sure it is not true. If you are a Christian you ought to bear in mind that the Lord and Master honored you by saying, "Ye are the salt of the earth." Now, my friend, how in the world are you going to make the world better if you don't know the world? Get acquainted. Let the children play with the neighbors' children. There is danger of their learning bad things and bad talk, I know; but, my friend, if you are watching and praying—if you are praying for your neighbors as well as for

the little ones of your own household, I think you can manage so there will not be any danger. Do not let the children go to such an extent that you don't know where they are nor how long they have been gone; but bear in mind that the little ones can help to save mankind as well as those grown up.

Now, if you say you have not any enemies, I shall think one reason is you are not very much acquainted, and that you are not very progressive. Get acquainted. See what is going on; find out why it is that our penitentiaries are constantly becoming larger; see where the seeds of crime start. If there are none at enmity with yourself, there are enemies of Christ that need looking after. They need looking after and feeding. Do you remember how Jesus told Peter, over and over again, "Feed my sheep;" and, "Feed my lambs"? My friends, there are those among your acquaintances who need feeding now. If you are hungering and thirsting after righteousness, there is abundant need that you should be up and doing. If you are longing for the time when Christ's kingdom shall come, and his will be done on earth as it is in heaven, set about hastening the glad day by enlisting in his service; and when you feel inclined to say there is nothing you can do, read over again this 20th verse of the 12th chapter of Romans:

If thine enemy hunger, feed him; if he thirst, give him drink; for in so doing thou shalt heap coals of fire on his head.

A LETTER FROM THOMAS HORN TO HIS CREDITORS.

AN EXPLANATION AND AN APOLOGY.

A CARD:—To my Customers, and Bee-Keeping Friends. As you know, friend Root has kindly gathered all claims and complaints against me, and sent me the same; and to say that they surprised me would but faintly express my feelings. I thought friend R. hard on me; but I certainly, under the circumstances, must ask his pardon for such thoughts.

Now, friends, let me explain, as nearly as I can, just how the case stands. Business pressed so much that it was utterly impossible to attend to the mail myself, and my order to my book-keeper was to answer all complaints; and if the goods could not be sent, to return the money; and I find very many of the complaints received are marked in his hand sent. Whether the errors were his or the yard help, I can not say, as I was so pressed for help that I had to use inexperienced help, and, I am sorry to say, as matters turn out, it was careless help, and many goods must have gone astray, or have been sent to other parties than they were intended for. When the season closed it found me with some complaints that had not been looked to, and, I am sorry to say, some orders that had not been filled or cash returned. I would then have returned to every one his money, but was unable to do so. Owing to the use of inexperienced help, expenses far exceeded my income; and, owing to other losses, it left me with no capital and plenty of experience; but through the kindness of friend Root, and encouragement of many of my old cus-

tomers, and assistance of friends, I am going to continue the struggle on a new basis, attending to the mail myself, and employing none but competent help in the yard. As to complaints and claims, I will pay every penny with interest, but must have time to do so. I shall pay them just as rapidly as I possibly can. Asking your patronage, I am yours very truly.

THOS. HORN.

Sherburne, N. Y., Apr. 7, 1887.

In a private note accompanying the above letter, friend H. says:

I am preparing the notes just as rapidly as possible, and will finish this evening so as to go out in to-morrow's mail.

THOS. HORN.

We presume from the above that our friends have, by the time this reaches them, Mr. Horn's note for the amount due.

Now, friends, there is a valuable lesson to be learned from the above. Be very careful how you undertake to do business, or to sell goods of any kind, at a less price than they can be afforded. If you think you can furnish some suitable commodity at a lower price than it has been yet offered at in the market, try it on a small scale first. Put in a modest advertisement, and be very careful about bringing responsibilities upon yourself that you are not able to carry. There is a certain limit to what any one man can do; and when this limit is passed, and he is obliged to employ hired help, experience usually indicates he must receive a larger price for his produce than where he can attend to it all himself. It is indeed a fearful thing to be placed where friend Horn is placed just now. Instead of receiving pay for his produce, as the rest of us do, long years must likely be spent in hard labor to make up for the losses of only a few months, consequent upon selling goods at a price that did not pay expenses.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

MEDINA, APR. 15, 1887.

Do good to them that hate you.—MATT. 5:44.

OUR FRIEND T. S. HALL.

MR. HALL is now located at Corinth, Miss., and wishes us to say that he is now prepared to fill his orders of last season that were not completed, and that he has 200 colonies from which to take bees, queens, etc.

BUSINESS AT THIS DATE.

WE are having a larger trade now than we perhaps ever have had before, at this season of the year. We are pretty well up with our orders, but on a few things there is necessarily some delay;

and especially is this the case with sections. As the present dry weather is, however, wonderfully favorable for seasoning the contents of our lumber-yard, we hope very soon to be able to report that we are up with orders once more.

MARCH WEATHER IN FOREIGN COUNTRIES.

From the *British Bee Journal* of March 31, we take the following:

The present March will long be remembered as one of the most severe on record. Frosts, snowstorms, snow lying to a depth of eighteen inches, gales, almost hurricanes, have prevailed; and 25 degrees of frost have been registered, sufficient, we fear, to kill in many cases the embryo buds on the fruit trees, if not the embryo brood in our hives. But we have only neighbors' fare, since we are told that the experience is the same "from Northern Denmark to Southern Spain."

YOUNG CARP IN APRIL.

THIS 12th day of April we see hundreds of little carp in our pond, from the size of a cucumber-seed up to those an inch in length. Now, I wish some of the veterans would tell me where these little chaps come from. The month of March was altogether too cold, according to the books, for spawning and hatching; and the question is, Were these little fellows hatched last fall, or have they got so big already this spring? Now, please do not ask me to sell some, for I do not know how to catch them. Besides, we are ever so much too busy with our regular work at this time of year. There ought to be some way of sending little carp by mail. In the winter we had some of the little chaps in the greenhouse, in a tank under the central bed, and they became so tame they would eat crackers out of my hands just as freely as a lot of chickens. If it were not for the trouble of catching them out of the pond, it seems to me they could be raised and sold almost as cheap as cabbage-plants; then may be they could be mailed short distances in damp moss. Suppose some of the carp-journals work out this matter. Why not have little fishes by mail, as well as queen-bees?

SIMPLICITY HIVES WITH BEVELED EDGES.

INASMUCH as quite a number of the bee-friends have complained of the beveled edges at the tops and bottoms of the Simplicity hives, and have suggested that these beveled edges were unnecessary, it may be well to explain that the hives as first used were used one over the other, with plain square joints. Mr. Langstroth, however, decided that such a joint was defective, for he made his upper stories to slip over the lower ones, resting them on a strip nailed on. The principal thing that determined me to have a better joint was the many and very grievous troubles I had from robbers getting through the ordinary square joint. So many losses resulted from this cause alone that I decided, cost what it would, I would have no more hives with cracks that could possibly let a bee through, even if one hive were carelessly set over another. The Simplicity and chaff hive both stop this nuisance entirely. Many experiments also satisfied me that rain, wind, and frost, can not be kept out as they should be, with plain square joints. Of course, bees will, in the fall, fill these joints with propolis; but when the hives are changed about, this very propolis makes it worse than before, unless we scrape it off laboriously. I do not believe that those who have been in the habit of using hives with the Simplicity joint will be satisfied to go back to the plain square joint. In any case, I would test a few before having hives made in any considerable quantity on the latter plan.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

FOUL BROOD; SUCCESS IN WINTERING; HONEY-BOARDS.

SHORTLY after GLEANINGS for last issue was out, the weather became sufficiently warm, so that I told the boys to go through the colonies, examine every comb, and watch sharp for foul brood. In the evening of the same day I sat at my desk in the corner, reading over matter for GLEANINGS, when all at once the door opened, and Mr. Spafford stepped in and said:

"Well, I have found another case of foul brood."

"Is it possible?" I said.

Together we went down to the colony in question. Yes, that very colony had been treated for foul brood late last fall, by the plan we have described in GLEANINGS. The worst part of it all was, that it reappeared, and that, too, in a clean new hive. Of the 60 cases that we had treated last fall, all were apparently cured, and we were going to put it down in the A B C book that the plan we practiced was a success in every instance; but this one colony, unless we made a mistake in its manner of treatment, seemed to be an exception to the general rule. However that may be, we can not tell.

Uncertain as to what should be done, I started toward the paternal mansion, to lay the matter before father and Dr. Miller (the latter was spending a few days here at that time). The family were just sitting down at tea. Although the hive containing the foul-brood colony was a new one, I inquired whether it would not be best to do with this as we had done with the other; that is, burn it—hives, bees, frames, combs, and all. Dr. Miller and A. I. R. agreed that, as this was apparently the only colony in the apiary, with foul brood, complete extermination was by far the safer way. Accordingly, with Mr. Calvert's assistance, I carried the hive over to the furnace that evening, threw in the combs, smashed the hive to pieces, and dumped it into the fire. We both said it seemed too bad to burn a brand-new hive and such nice-looking bees; but we doubt if, under the circumstances, many of our readers would have done otherwise. If but one or two more cases shall yet appear, we don't propose to give them any thing milder than this heroic treatment. If, on the contrary, one-fourth or one-third of the colonies were diseased, and we have reason to believe that foul brood was scattered all over the apiary, we should try the milder treatment as we did last summer and fall. The complete extermination of forty or fifty colonies would be, in this case, a little too severe.

APRIL 11.—NOT A SINGLE COLONY OF THE 200 LOST.

As there is a brighter side to almost every thing, I will now give you some facts which make us feel greatly encouraged. For the last week the apiary has been examined almost daily, and no foul brood has been

found. More than that, at this date, April 11, we have not lost a single colony by wintering. Taking into consideration the fact that so many of our colonies had been reduced last fall by foul brood, and, in consequence, were very weak; and taking into consideration that we commenced feeding rather late in the season, and consequently fall brood-rearing was not carried on; we think we have a good deal to flatter our vanity. Not only were no colonies lost, but every one seemed to be as strong, and in many cases stronger, than when put into winter quarters late last fall. Unless we have some pretty severe weather, I think we shall be able to record in next issue that the Home of the Honey-Bees has wintered over 200 colonies during the winter of 1886-'7 without the loss of a single one.

THE SLATTED HONEY-BOARD, AND HOW TO USE IT.

The advent of the Moore crate and the T super—in fact, all kinds of section-crates used above the brood-chamber, has made the use of the Heddon slatted honey-board almost a matter of necessity. The construction of the Simplicity hive is such that an ordinary slatted honey-board to slip inside (such as we have heretofore advertised) can not be used between the stories of our regular Simplicity hives without interfering with the frames above when the hive is run for extracted honey. However, it was all right for comb honey. The problem, then, which we have been trying to solve for the past three or four months was, "How shall we construct a honey-board so that it can be used in a Simplicity hive, exactly as we have made and sold it for years back, without interfering with the frames for extracting, or the double-tier wide frames?" Let me explain to you more exactly the real point we had at issue.

For illustration, let us take a two-story Simplicity hive; put into it 10 frames below and 10 above. We insert between the two stories, to prevent the queen from laying in the upper set of frames, and to prevent burr attachments, a wood-zinc slatted honey-board. As the hive is constructed with the beveled edge, there is $\frac{3}{8}$ of an inch between the upper and the lower set of frames. The honey-board is $\frac{1}{2}$ inch thick at the ends. We will now put in the slatted honey-board, and see what the results are. We find that the upper set of frames are raised off the rabbets just $\frac{1}{4}$ of an inch. We conclude, therefore, that this will not do. We have formerly told our customers to slip into the rabbet a strip of wood wide enough to raise the upper set of frames the proper distance above the slatted honey-board.

We will next arrange the two-story Simplicity hive for *comb honey*. To use either the Moore crate or T super we put in the honey-board, pile on the two crates, slip the body over, and all is well, *providing* the bee-space in the crates or supers is below the sections. Our old honey-board has a bee-space below it, but none above, and it is this particular honey-board that we have been discussing thus far.

Now, in discussing the proper construc-

tion of the T super recently, our readers will remember that Dr. Miller and others recommended most strongly that the super be made with the bee-space *on top*, and not below. At the very outset it was evident that the old honey-board could not be used with the T super having a bee-space *above*, for the simple reason that the super would rest right on the honey-board without any space between them. As the arguments came in so thick and fast, showing the advantage — indeed, we might say the *necessity* — of putting the bee-space above the sections, it became evident that we should have to construct our honey-board with a bee-space above and below, or, as Mr. Heddon terms it, I believe, a “sunk” honey-board. This would necessitate making the ends of a honey-board $\frac{1}{2}$ inch thick. By putting such a honey-board on the hive, we discover that the *upper* story Simplicity would not go on, on account of the bevel on its under edges. Well, then we said we would bevel off the ends of the honey-board, as seen in the engraving. We did so, and the upper-story Simplicity body fitted on all right. Below we give a view of the honey-board, shown at the left, the ends beveled in such a way as to fit under the bottom edges of the Simplicity upper story.

SLATTED-WOOD-ZINC HONEY-BOARD, WITH RIM FOR SIMPLICITY HIVE.

You observe, also, that the slats are “sunk” so that the honey-board itself furnishes a bee-space above as well as below. In other words, it is now adapted to the super with the bee-space above. To give you an idea of how the slats are fastened to the end-pieces, we give you a cross-section of the end. Let *A* be the end of a slat, and *B* a cross-section of the end of the honey-board, as shown in the accompanying diagram. The slat *A* slides into the mortise *a*. In putting together, we take the full number of slats required, and slide them into the mortise, or groove *a*. When all are in, a couple of side pieces, as shown in the engraving, are nailed to the ends. One nail through each slat, starting at the point *c*, holds each slat firmly in place. To make this honey-board queen-excluding, saw-kerfs are made in each slat, and the strips of perforated metal are slid in between the slats.

So far we have arranged for the bee-space in the T super, as recommended by Dr. C. C. Miller and others, and this honey board can be used with all the supers that we now make with the bee-space on top in the Simplicity hives, and every thing will be well; but if we desire to run our Simplicity hive for extracted honey we shall find the same difficulty that we mentioned before, only

worse than ever. That is, if we use the honey-board as shown in the engraving at the left, and put it between the upper and lower set of frames, it will raise the latter $\frac{1}{2}$ inch above the rabbet. In order to remove this difficulty it becomes necessary to raise the Simplicity body just high enough so as to leave a bee-space between the upper set of brood-frames and the honey-board; hence we make use of the beveled frame shown in the right of the engraving. This frame is so made that it fits exactly between the upper and lower story. You notice that the frame is a trifle larger than the honey-board; that is, it is of just such a size as will slip snugly around it. Right here I presume some of you will suggest, “Why not fasten this rim permanently to the honey-board — in other words, make it part and parcel of it?” In theory this seems quite an easy thing to do; but here, again, the beveled edge presents practical difficulties that make it desirable and better in every way to have the honey-board and the rim separate. In the production of comb honey the rim is not necessary, and probably a large number of those who are working for extracted honey would not care to use the honey-board at all. The whole thing resolves itself into this: That the rim is not necessary in the production of *comb* honey; and for the few who desire to use honey-boards in the production of extracted honey, it hardly seems fair that the larger number composing the other proportion of honey-producers should be made to bear the extra expense of making this outer rim a part and parcel of the honey-board itself.

Here, again, I begin to suspect that some of you will suggest, “Why not dispense with your old beveled edge (which, by the way, is a perfect nuisance), and make your slatted honey-board in outside dimensions equal to the outside dimensions of the hive, just as Mr. Heddon and others make and use it?” In answer to this we would say that, even granting for argument’s sake that the beveled edge is not a necessary feature, there are hundreds of thousands who are using this same “naughty” beveled edge; and if we change and make all our hives with a square joint, the new Simplicity hives will not be interchangeable with the old ones; but we believe the honey-board, as illustrated and described above, is one which fills the bill as nearly as possible under the existing circumstances. So important did we consider the proper construction of the honey-board for the Simplicity hive, that, at Dr. Miller’s suggestion, we asked him to “come over and help us.” When he arrived here, upon full and careful consideration he said that this honey-board was the only one that could be used with the *beveled* edge. I will say, in this connection, that we had a number of good talks from Dr. Miller on hives and hive construction; and if he has not “led us out of the woods,” as friend Drew puts it, on this beveled edge, he has on quite a number of other things. The result of these long talks, and the candid criticisms presented by the doctor, will probably result in a mutual benefit to us all.

SPECIAL NOTICES.

PRICE OF THE NEW SLATTED HONEY-BOARD.

Our improved slatted honey-board as shown and described on page 321, with and without the strips of zinc, will be the same price as formerly; see page 22 of our catalogue. When the rim is desired, the price in flat will be 3c each; 45c for 10, or \$4.00 per 100.

WOOD MATS.

We have discontinued making the wood mats that we have sold for a number of years, and have not advertised them in our catalogue for nearly a year. We have stopped making them because we could not recommend them, as, when they are stuck fast to the frames, and you wish to remove the mat, it jars each frame as it is withdrawn, and irritates the bees. We like our enameled sheets so much better that we will send them hereafter instead of the wood mats.

MAPLE SUGAR.

The maple sugar and syrup of this year averages better throughout than we ever knew it to before. There is also a good deal of it just around here where the maples are plentiful. Because the quality is so much better throughout, the different grades that we make will, of course, be of better quality than heretofore; that is, you will get better sugar for the same money. We have a very fine large stock of the three grades—10, 9, and 8 cts. In 50-lb. lots, ½ cent less. In barrel lots of about 280 lbs., 1 cent less. If you want more than a barrel, write us for special prices.

PEAVINE CLOVER-SEED REDUCED.

Although alsike has gone up to the old price, \$8.00 per bushel, we are glad to announce that, for a limited time at least, we can furnish Peavine, or Mammoth clover-seed, at the following very low prices: \$5.00 per bushel; \$2.60 per ½ bushel; \$1.40 per peck; 12 cts. per lb. I don't know how long these prices will last; but if the price advances again, we shall, of course, have to charge more. We have secured a nice lot of alsike seed, and we are glad to say our prices will not have to go any above our last announcement—\$8.00 per bushel.

ADVANCE IN THE PRICE OF BEE-VEILS.

When we reduced the price of bee-veils last summer it was because we got a cheaper and poorer quality of grenadine to make them of, not being able at the time to get any thing better. We have just recently secured a very large lot of fine grenadine, and we are obliged to advance the price of bee-veils again to the following prices: Grenadine veils with brussels-net face, 60 cts.; all-grenadine veils, 50 cts. Mosquito-bar veils with brussels-net face, 40 cts.; veils made entirely of mosquito-bar, 25 cts. Prices in lots of 10 will be \$4.50, \$4.00, \$3.20, and \$2.00.

SECOND-QUALITY SECTIONS.

We are constantly getting orders for second-quality sections, which we can not fill. We do not advertise nor agree to furnish such sections; and the way our new lumber is turning out, we shall not have any to spare this season. Our basswood lumber, cut the past winter, which we are beginning to work up into sections, is turning out some of the finest sections we ever saw, being almost as white as the paper on which this is printed. We have been very careful in the selection of our lumber, and careful, also, to have it cut the right time of year. This naturally makes the culs very scarce, and it is only the culs that we sell for second-quality sections. If we receive orders for second-quality sections we shall be obliged to send first-quality or none. Please remember this in making your orders. I think, as a general rule, you will find that comb honey will sell enough better, in nice white sections, than in culs, to justify you in paying the extra price. Of course, there may be a few exceptions to this in the home market; but where honey is sent off to the towns and cities it will certainly sell better when the sections are clean and white.

A SPECIAL LOT OF 1½-STORY SIMPLICITY HIVES.

We have recently made a large lot of Simplicity hives, which consist of a regular Simplicity body, ½-story cover, and cleated bottom-board, which

projects in front of the hive about three inches, to form an alighting-board. In front end of the bottom-board is cut a half-circle ⅝ of an inch deep, to form an entrance to the hive when the body is slipped forward on the bottom. These hives are put up 10 in a package. Now, the price of the regular Simplicity 1½-story hive with alighting-board and bottom-board is \$7.00 for ten; but we will sell this special lot, which is equally good as the regular Simplicity 1½-story hive, for \$6.50 for ten. That will make the price the same as ten 1½-story portico hives, or ten-crate number 4. These hives were made for a foreign order which was received through a New York house, and they, in copying the order, wrote 1000 instead of 100. When you order these hives, please order them by the name of "10-crate No. 5." When 1½-story Simplicity hives are ordered we will send these hives to fill the order, unless you specify that you do not want them. They are really better than the regular 1½-story Simplicity hives with bottom-board, because you have an alighting-board extra, without extra charge. If these hives please as well as we expect them to, we shall probably keep them in stock.

CONVENTION NOTICES.

The next meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association will be held at Rockton, Ill., May 24, 1887.
D. A. FULLER, Sec.
Cherry Valley, Ill.

The ninth annual meeting of the Texas State Bee-Keepers' Association will be held at the farm of Judge Andrews, near McKinney, Collin Co., Texas, May 4 and 5, 1887. Bee-keepers of Texas, come out! and all other bee-keepers are fraternally invited to be with us. No hotel-bills to pay.
B. F. CARROLL, Secretary.
Dresden, Tex.

ITALIAN QUEENS. WARRANTED TO
GIVE Satisfaction.
TESTED, \$2.00; UNTESTED, \$1.00, after May 15, 1887.
R. W. TURNER, Medina, Ohio.

INDIANA.—Headquarters for pure **ITALIAN QUEENS.** At prices that will surprise you. Write us for catalogue and full particulars.
MARTIN & MACY, North Manchester, Ind.
Eggs from high-class poultry for sale.

Recent Additions to the Counter Store.

FIVE - CENT COUNTER.

- | | |
|---|-----------|
| 4 DARNING-BALL, black enameled | 40 3 80 |
| These are the shape of a large egg, with a handle in one end. In the end of the handle is a place to keep needles. Handy for darning stockings. | |
| 2 BUTTON-HOOK, steel, with ivory handle | 45 4 40 |
| 2 BLOW-PIPE, 7 in., used by jewelers..... | 46 4 50 |
| Made of brass, and usually sold for a dime or more. | |
| 3 BASEL FOR CUP AND SAUCER, silvered wire. | 40 3 80 |
| Sets off your china cup and saucer to good advantage. | |
| 3 SOAP-STAND, silvered wire..... | 40 3 80 |
| Very pretty and useful. | |
| 1 HANDKERCHIEF, BORDERED | 45 4 40 |
| Fancy colored or mourning borders, hemmed. | |

TEN-CENT COUNTER.

- | | |
|--|-----------|
| 2 POCKET-COMB, either folding-rubber, or horn with mirror..... | 80 7 50 |
| 2 NEEDLE-PACKET | 80 7 50 |
| Consists of 4 papers of assorted needles and some large sizes. | |
| 2 WATCH-CHAIN, white metal..... | 90 8 50 |
| Cable pattern. Looks and wears like silver. | |

FIFTEEN - CENT COUNTER.

- | | |
|---|--------------|
| 3 INDELIBLE INK for marking linen .. | 1 40 13 50 |
| This is universally sold for 25 cts. per bottle, but we have decided to give you the benefit of the extra 10 cents. | |

TWENTY-FIVE CENT COUNTER.

- | | |
|---|--------------|
| 5 SUSPENSERS, elastic, nickel trimmed | 2 20 20 00 |
| Some have thought our 10-cent suspenders too cheap, so we have got some good enough for a king, for 25 cents. | |

THIRTY-FIVE CENT COUNTER.

- | | |
|--|--------------|
| 20 SPICE-NEST | 3 00 28 00 |
| Six neat little spice-boxes, with the name in gilt in a neat frame, all of japanned tin. | |

FIFTY-CENT COUNTER.

- | | |
|---|--------------|
| 1 WINDOW-SCREEN FRAME..... | 4 00 36 00 |
| These are put together with castings at the corners, and can be made to fit almost any window. They are grooved at the side, to slide up and down on an iron that goes with them. | |
| 3 WATCH-CHAIN, white metal—beauties | 4 00 38 00 |
| Assorted patterns, with drop. They look and wear like silver, and are warranted solid "Albino" white metal. | |

JOB LOT OF POULTRY-NETTING.

Small Pieces at same Rate as full Rolls — 1 ct. per Square Foot.

Two or more pieces, 5 per cent off; ten or more, 10 per cent discount.

You will notice in this lot some with heavier wire than No. 19, and some with smaller mesh than two-inch. Both of these are worth more at regular prices than two-inch No. 19; but as it is a job lot we put it all in at the same price.

By dividing the number of square feet in this column by the width in the first column, you can ascertain the length of each piece. These figures give the number of square feet in each piece.

Inches wide.	Inch mesh.	No. of Wire.

We know of nothing nicer or better for a trellis for creeping vines than the above netting. The 12 to 24 inch is just the thing to train up green peas, fastening the netting to stakes by means of staples. If the stakes are set in substantially, one each 12 or 15 feet will answer. When the peas are stripped off the stakes, netting and all can be rolled up and laid away until another season.

Bee-Hives, Sections, & Frames

As I am located where an abundance of basswood and pine grows, I feel safe to say I can furnish my goods as cheap as they can be produced.

A. I. Root Chaff Hive a Specialty.

All goods warranted. For reference, apply to the Bank of Clintonville, Wis. 47fdb

The "Gilt Edge" Apiary offers Italian queens from imp. mother; untested, in April and May, \$1.00; unt'd, in June and after, 75 cts. Tested queens double above price. A. P. STAIR, 5-10db Whitney, St. Clair Co., Ala.

E. M. HAYHURST'S FINE ITALIANS.

\$4.50 TO \$5.50 PER COLONY:

On account of ill health I have decided to sell my **Queen-Yard** this season, at the following prices: One full colony, \$5.50; two or more, \$5.00 each. These bees are in one-story, ten comb Langstroth hives; have fine young tested queens, and a reasonable amount of brood and bees, with honey for the trip; are perfectly healthy, no foul brood in my yard or neighborhood; they are extra fine stock, and first-class honey-gatherers. If wanted in rough shipping-box instead of hive, the price will be 50 cts. per colony less than above. Safe arrival guaranteed. Will begin shipping about May 1st.

PASTEBOARD BOXES

FOR ONE-POUND SECTIONS OF

COMB HONEY.

This box has a bit of "red tape" attached to it to carry it by. It makes a safe package for a single section of honey for the consumer to carry, or it can be packed in a trunk, if he wants. It can be opened in an instant. The price of the box is 2 cts. each, set up; in the flat, 15 cts. for 10; package of 25, 30 cts.: \$1.00 per 100; or \$9.00 per 1000; 10,000, \$80. If wanted by mail, add \$1.00 per hundred for postage. Colored lithograph labels for putting on the sides, two kinds, one for each side, \$3.00 per 1000. A package of 25, labeled on both sides, as above, 50 cts. By mail, 30 cts. more. They can be sold, labeled on one side or both sides, of course. We have only one size in stock, for Simplicity sections. Sample by mail, with a label on each side, 5 cts. If you want them shipped in the flat, labels already pasted on, the price will be ten cts. per hundred for putting them on.

Your name and address, and the kind of honey, may be printed on these labels, the same as other labels. The charge for so doing will be 30 cts. per 100; 250, 50 cts.; 500, 75 cts.; 1000, \$1.00.

A. I. ROOT, Medina, Ohio.

RUBBER STAMPS

DATING, ADDRESSING, BUSINESS,
LETTER HEADS, ETC.

No 1.

No 3.

No. 2.

Address only, like No. 1, \$1.50; with business card, like No. 2, \$2.00; with movable months and figures for dating, like No. 3, \$3.00. Full outfit included—pads, ink, box, etc. Sent by mail postpaid. Without ink and pads 50 cts. less.

Put your stamp on every card, letter, paper, book, or anything else that you may send out by mail or express and you will save your

self and all who do business with you a "world of trouble." I know, you see.

We have those suitable for druggists, grocery-men, hardware dealers, dentists, etc. Send for circular.

WANTED.—To exchange eggs from pure-bred Langshan fowls, for beeswax, tested Italian queens, wood revolver, or any thing useful.
6d E. P. ALDREDGE, Franklin Square, Col. Co., O.

WANTED.—To exchange bees by the pound or full colonies, queens, comb fdn., eggs for hatching from L. Brahmas and S. S. Hamburgs, for sections, Jersey cow, American Merino sheep, or offers.
6-7-8-9d J. P. STERRITT, Sheakleyville, Mercer, Co., Pa.

WANTED.—To exchange 80 colonies of bees in chaff and Simp. hives, of 10 wired fdn. frames each, for some good land near by. Apply at once.
7 8d JAS. H. ANDRUS, Almont, Mich.

WANTED.—To exchange Wyandotte eggs, pure ground bones and shells, and Gregg raspberries, for comb foundation.
7-8-9d A. A. FRADENBURG, Port Washington, O.

WANTED.—To exchange metal cornered, wired frames (Simp.), ready to hang in the hive, filled with foundation, for Italian bees and queens.
7-8d R. B. BONEAR, Cherry Ridge, Pa.

WANTED.—To exchange Barnes foot-power saws and bees, for steam-engine, honey, or beeswax.
7-12db C. W. & A. H. K. BLOOD, So. Quincy, Mass.

WANTED.—To exchange a small self-inking printing-press, large enough to print postal cards full-size, for high-class poultry or raspberry-plants. Write for terms of exchange.
8d W. S. DORMAN, Mechanicsville, Ia.

WANTED.—Bee-keepers' supplies; a good, moderate-sized incubator; eggs for hatching; pure-bred pigeons, pheasants, etc.; for which I offer dry goods (of almost any kind). Samples on application. Please state what you want and what you have to offer.
8-10d WALTER SHERMAN, Newport, R. I.

WANTED.—To exchange one pair each "Silver-Spangled Hamburgs and Brown Leghorns, for fdn., or offers of bees by lb.; also, one silver watch to trade on a fdn.-mill (10-inch preferred), or will exchange for comb honey, Italian bees, or offers.
8d C. L. HILL, Dennison, O.

WANTED.—To exchange a Priham Foundation mill for honey; and fdn. for beeswax.
8-9d J. Q. A. HAUGHEY,
Box 2390, Battle Creek, Mich.

WANTED.—To exchange an English microscope, new, and 12 mounted slides, showing the different sections of the honey-bee. Cost in England \$10. I will take bee-hives or any useful thing for the apiary.
WM. N. BAILIE,
8d Box 845, Carbondale, Pa.

WANTED.—To exchange 30 or 40 swarms of bees for Jersey cow; I also have a few Bronze turkey-eggs, A 1 stock.
L. GORTON,
15d Salem, Washtenaw Co., Mich.

WANTED.—To exchange a foot-power former (Barnes'), a B-flat cornet, and 20 two-story Simplicity hives, for bees or offers.
8d CYRUS MCQUEEN, Baltic, O.

WANTED.—To exchange a Cyclostyle and a No. 2 Caligraph for bees, supplies, and part cash.
M. G. BAXTER, Uhrichsville, O.

WANTED.—To exchange complete photograph outfit for Army newspaper press or job office.
8-9d WALTER A. KALER, Andersonville, Ind.

WANTED.—To exchange eggs (Wyandotte, Light Brahma, and Buff Cochin) for hatching, for fdn. or sections. The fowls are all high strains.
8d M. D. HUGGINS, Davenport, Ia.

WANTED.—To exchange bees or queens for registered Jersey heifer.
8fdb ISRAEL GOOD, Sparta, Tenn.

Wanted. A good bee-keeper to take charge of my apiary of 121 colonies, on shares.
ROBERT BLACKLOCK, Killgore, Carter Co., Ky.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

After the 15th of May I will have 30 black and hybrid queens that I will sell for 25c each. These are good prolific queens, and well worth the amount.
W. S. DORMAN, Mechanicsville, Iowa.

For Sale.—A number of good hybrid queens at 25 cts. each.
L. HARRIS, Box 304,
Greenville, Bond Co., Illinois.

For Sale.—Hybrid queens at 50 cts. each; blacks, 25c. I can ship by return mail. We have some 50 now.
T. S. HALL, Corinth, Miss.

Hybrid queens, reared from select tested Italian mother, for sale at 50 cts. each. Safe arrival and satisfaction guaranteed. GEO. W. BECKHAM,
8-9-10d Pleasant Hill, Lancaster Co., S. C.

I will sell on or after April 15th, 10 hybrid queens at 50 cts. each. Taken from swarms I bought last fall.
G. A. BEECH, Quitman, Nodaway Co., Mo.

I have a lot of hybrid queens for sale. Price 50c. in April-May; 70c. Safe arrival guaranteed.
H. M. MOYER, Hill Church, Berks Co., Pa.

❧ A * WHEELBARROW * FOR * BEE - KEEPERS. ❧

ALSO A WHEELBARROW FOR WOMEN, CHILDREN, AND
PEOPLE WHO ARE NOT VERY STOUT.

OUR 35-POUND WHEELBARROW, CAPABLE OF CARRYING 500 POUNDS.

them at their convenience, when times were dull. Well, friends, the wheelbarrows are here, and they are a surprise to everybody. We show you a picture above. We have two sizes—the smaller one weighing only 35 lbs., and yet it will carry 500 lbs. safely, and it can be packed so closely together for shipment that you can take the whole thing under your arm and walk off easily. The wheel has flat spokes instead of round. The different pieces are all cut and forged by means of dies. The legs are steel, so they will neither break nor bend, even if you bump them on the sidewalk. The springs are oil-tempered, with adjustable bearings, so you can tighten them up for wear. More than all, the wheelbarrows are the nicest job of painting and varnishing I believe, I ever saw, for a farm implement. They are handsome enough to go around town with, and strong enough to do heavy work; and yet the price of the small size is only \$4.00, the same as our iron wheelbarrow. The larger size is \$4.50. The only discount that can be made is 5 per cent off for two; 10 per cent off for five, or 15 per cent off for ten or more. They can be sent either by freight or express. It is only five minutes' work to put one together.

A. I. ROOT, Medina, Ohio.

I have several times felt as if I should like to try my hand at making a wheelbarrow of our strongest wood and our best steel, properly braced and arranged so as to give strength, and yet not weigh one ounce more than is absolutely necessary. At the Ohio State Fair last year I found a wheelbarrow that came so near filling the bill that I asked the manufacturers how cheaply they could make 100. The wheelbarrow was all I could desire; but the price, I thought then, was more than we could stand. During the winter, however, they made a proposition which I considered very reasonable, providing they could make

KIND WORDS FROM OUR CUSTOMERS.

I received the goods all right; thanks for promptness. Wife is well pleased with her poultry-book.
Blaine, Ohio. L. C. SEABRIGHT.

I got an A B C from you about six or seven years ago, and I like it better every time I look at it; in fact, it suits me the best of any thing on bee culture that I have seen yet. W. ATKINSON.
Cheapside, Ont., Can., April 7, 1887.

CAN'T BE BEAT.

Goods received all right. Many thanks. My wife thinks the thimble is just a daisy. The boy is delighted with the knife, and I think the saws can't be beat. J. BARLOW.
Sac City, Iowa.

OUR CARPET-SWEEPERS.

Goods arrived in good order. The carpet-sweepers are beautiful, and very cheap. The price of a similar machine here is \$3.50. Every thing is satisfactory, as usual with goods ordered of A. I. Root.
Middletown, Conn. C. H. LEWIS.

FIVE CONCORD GRAPEVINES.

From five Concord, four years old, last season, I got 300 lbs. of grapes. I think your A B C is a very nice book. It is interesting; anyhow, it is a book whose merits one can judge of by experience.
Buffalo, N. Y., Mar. 9, 1887. JAMES ROBINSON.

200 LBS. OF WAX FROM ONE OF OUR MACHINES IN HALF A DAY.

I received the foundation machine the 30th of March, all completed. It gives good satisfaction. I have rolled out 200 lbs. of wax in half a day. JOHN THILB.
Santa Monica, Los Angeles Co., Cal., Apr. 9, 1887.

STEREOSCOPIC VIEWS.

The goods arrived all right. The children say I must write you and tell you how pleased we all are with the stereoscopic views. All the goods gave entire satisfaction as usual. My bees are doing well. I am trying to be ready to fill your order for queens by return mail. J. D. FOOSHE.
Coronaca, S. C., Mar. 8, 1887.

A KIND WORD FROM J. E. POND.

My son, 17½ years old, has accepted Christ for his Savior, and I do think that GLEANINGS and you had much to do with it. The Home Papers drew his attention to the matter; at any rate, he is today a Christian, and I know that you will rejoice with me thereat. I tell you, Mr. Root, you don't know the good you are doing, and will never know it till the last day. J. E. POND.
Foxboro, Mass., Apr. 7, 1887.

"MAPLE SYRUP DECIDEDLY RICH."

Sections and maple syrup came to hand all right. The maple syrup is decidedly rich.

J. F. MICHALL.

German, Darke Co., O., Apr. 7, 1887.

FRAMES, NICEST EVER SEEN.

The box that did not come with the others has arrived with every thing satisfactory. The frames are the nicest I ever saw. My bees all answer to roll call, and in fine condition. M. C. YOUNG.
Centertown, Pa., Apr. 9, 1887.

PLEASED.

The goods ordered of you some time back arrived here all right. Let me express my heartiest thanks to you for always filling my orders so promptly. That brood fdn. is, I think, just the thing. The reversible frames, I think, will just answer to the roll. MATTHIAS SCHNEIDER, JR.

McIvor, Mich., Apr. 20, 1887.

GOOD MEASURE.

I received my goods the 15th of this month. Every thing came in good shape, and as it was ordered. Your goods have always been satisfactory since we have been dealing with you, which, I think, is ten years. You have a bigger bushel to measure your potatoes in than any seedsman I ever bought potatoes of yet. Your goods will recommend themselves. They are always put up neatly, and fit exactly. G. GASE.
Berwick, O.

[Friend G., the reason why we give good bushels is because we sell our potatoes by weight, 60 lbs. to the bushel. I have been trying to buy them by weight from those who advertise choice potatoes for sale, but I am sorry to say they don't hold out. A barrel is called three bushels, and most of us know to our sorrow that our barrels are of every imaginable size, and especially smallish when you are buying expensive varieties of potatoes by the barrel. Can't we have a reform in this matter?]

A FRANK APOLOGY.

Please find inclosed the amount for Terry's A B C of Potato Culture, which, if it is as good as its namesake on bee culture, should be in all farmers' hands. I owe you an apology which should have been made long ere this, but was neglected. About a year ago I sent to you for a queen. She came marked "untested Italian," but was, as I supposed from her appearance, black. I sent again for 2, which came all right; but I was ignorant enough to suppose all queens should be banded; and as this one was black I wrote you a rather severe letter, which I have regretted ever since, as she is the best queen I have. Her brood are all pure, and workers too. I sometimes think, when I see you getting "blown up" in GLEANINGS, that fully one-half of the mistakes are through the stupidity of such people as myself who are too prone to let the old nature assert itself instead of following the example of Him who, when he was reviled, reviled not again, letting his Spirit conduct and guide our every act. Now, brother Root, for though we shall never, in all probability, meet on this side of the great river, still I can claim you as a brother in Christ. I hope you will not weary in well doing, for eternity alone will reveal the number of those who have been encouraged and comforted through your instrumentality. W. J. KINCADE.

Kerwood, Ont., Can., Apr. 4, 1887.

[Very many thanks, friend K., for your kind expressions of me and my work, and especially for your very frank, straightforward apology. These kind apologies, after it is all over and perhaps forgotten, do us more good, sometimes, than kind words from a pleased customer. We hope all who read your letter will take a second thought before they enter any complaint.

We hope that all who have complained because the queens we sent out are not as yellow as many of the home-bred ones, will remember that the progeny of queens from Italy are not, as a rule, light-colored, some of them being almost black. The workers, however, are usually finely marked; and as honey-gatherers I do not know that there are any bees on the face of the earth any better than the progeny of Italians freshly imported from Italy.]

HONEY COLUMN.

CITY MARKETS.

PHILADELPHIA.—*Honey*.—Same as last reported.
April 22, 1887. PANCOAST & GRIFFITHS,
242 South Front St., Philadelphia.

ST. LOUIS.—*Honey*.—There is no change to report in honey. Market still dull.
April 22, 1887. W. B. WESTCOTT & CO.,
108 and 110 Market St.

DETROIT.—*Honey*.—Best white comb honey 11@12. Inferior grades very dull.
Beeswax, firm at 23c. M. H. HUNT,
April 22, 1887. Bell Branch, Mich.

CLEVELAND.—*Honey*.—There is an improvement in the demand for choice 1-lb. sections at 12@13c. Second quality dull at 10@11. Buckwheat unsalable at 8@9. Extracted, 5@6.
Beeswax,—25c. A. C. KENDEL,
April 21, 1887. 115 Ontario St., Cleveland, O.

BOSTON.—*Honey*.—Our maple sugar and syrup now interfere with the sale of honey, and we are having slow sales. White clover, 1-lb., 13@15; 2-lb., 11@13.
Beeswax, 26c. BLAKE & RIPLEY,
April 22, 1887. 57 Chatham St., Boston.

COLUMBUS.—*Honey*.—Market quiet.
White clover in comb - - - - - 14@15
" " extracted - - - - - 8@10
California comb honey - - - - - 10@12
" " extracted - - - - - 5@8
No. 1 white-clover honey is scarce in this market and is bringing full prices. Extracted is slow sale.
April 22, 1887. EARLE CLICKENGER,
Columbus, O.

CHICAGO.—*Honey*.—Honey is dull. Prices are weak. Best grades of white comb in one-pound sections, 11@12 cts.; any thing off from choice, 9@10 cts. Sections running over one pound, 8@10 cts.; dark, 7@8 cts. Extracted white clover and linn, 5@6 @7 cts., according to grade and package. Dark, 4@5. *Beeswax*, 25 cents. R. A. BURNETT,
April 21, 1887. 161 South Water St., Chicago, Ill.

CINCINNATI.—*Honey*.—There is a fair retail demand for choice comb honey, and extracted honey in square glass jars. Demand from manufacturers seems to be improving. We quote 11@14 cents for best comb honey in a jobbing way, and 3@7 cts. for extracted honey on arrival.
Beeswax is in good demand, and brings 20@23 cts. for good to choice yellow on arrival.
April 21, 1887. CHAS. F. MUTH & SON,
Cincinnati, Ohio.

KANSAS CITY.—*Honey*.—We quote white clover, 1 lb., at 11@12 cts.; dark, 1-pound, 9@10 cts.; white clover, 2-pounds, 10@11; dark, 9@10. The market in extracted is almost bare of white clover, also California. We quote at 5@6 cts. in small way.
Beeswax, 23@25 cts. CLEMONS, CLOON & CO.,
April 23, 1887. Kansas City, Mo.

CONVENTION NOTICES.

The next meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-keepers' Association will be held at Rockton, Ill., May 24, 1887. D. A. FULLER, Sec.
Cherry Valley, Ill.

The Keystone Bee-keepers' Association will hold its next annual meeting in the Court House at Scranton, Pa., May 10, 1887. All in the State and its immediate vicinity are invited to be present. Come one and all with your knotty questions. Interesting papers are expected from noted apiarists.
Clark's Green, Pa., Apr. 19, 1887. ARTHUR A. DAVIS, Sec.

The semi-annual meeting of the Progressive Bee-keepers' Association will be held in the Town Hall at Bedford, O., Thursday, May 5, 1887, at 10 o'clock A. M. Manufacturers of supplies for bee-keepers are requested to bring with them, or send, samples of their wares for exhibition. There will be a picnic dinner. All interested in apiculture are cordially invited to be present.
MISS DEMA BENNETT, Sec.
Bedford, Cuyahoga Co., O., Apr. 18, 1887.

CIRCULARS RECEIVED.

The following have sent us their circulars since April 1st. By an oversight, this department was omitted in our last issue. All the price lists are noticed hereafter, except those that have no date. See editorial, current issue.

J. O. Richardson, Walker, Iowa, an advertising sheet of bee-supplies.

F. J. Crowley, Batavia, N. Y., a 6-page circular of apiarian supplies.

J. P. Moore, Morgan, Ky., a 4-page circular of Italian queens and bees.

Joseph E. Shaver, North River, Va., an 18-page circular of bee-supplies.

G. D. Black, Brandon, Buchanan Co., Ia., a 6-page circular of bees and honey.

Ernst B. Hildeman, Ashippun, Wis., a 4-page list of potatoes and bee-supplies.

W. S. Dorman, Mechanicsville, Ia., a 4-page circular of bees and bee-supplies.

J. C. Bowman, North Lima, O., a 12-page circular of bees and Wyandotte fowls.

E. M. Hayhurst, box 60, Kansas City, Mo., an advertising card of bees and queens.

J. A. Green, Dayton, La Salle Co., Ill., an 8-page advertising sheet of bee-supplies.

Arthur A. Davis, Clark's Green, Pa., a 10-page circular of bee-supplies and windmills.

A. O. Crawford, South Weymouth, Mass., a 12-page price list of bee-keeping specialties.

R. B. Leahy, Higginsville, Mo., an 8-page (large size) circular of bee-keeping supplies.

P. D. Miller, Grapeville, Pa., a 6-page circular of Italian and Arkansas queens and bees.

D. Kaufman, Needy, Oregon, a 16-page list of apiarian supplies, and bees and queens.

J. T. Wilson, Nicholasville, Jessamine Co., Ky., an advertising sheet of Italian queens.

M. S. Koop, successor to A. B. Howe, Council Bluffs, Ia., a 20-page circular of bee-supplies.

John Hall, Station Hill, Wigton, Cumberland, Eng., a 6-page circular of bee-keeping requisites.

E. A. Sheldon, Independence, Ia., a list of apiarian supplies, printed on one of Martin's chromo cards.

H. H. Brown, Columbia, Pa., a 20-page circular of Italian and Cyprian bees, comb foundation, extractors, etc.

A. L. Swinson, Goldsboro, N. C., an advertising sheet of albino, American, and Italian queens. Also imported Syrians, Cyprians, and Carniolans, from Frank Benton.

THE T-SUPER FEEDER, AND SOMETHING ABOUT ROBBING.

C. C. MILLER REPLIES.

I NEVER had any doubts as to the value of the remarks by the editor of GLEANINGS, appended to the contributions of the various writers; but if I had ever had such doubts they would all be dispelled after reading the remarks at the close of my article on page 305. I can readily see how an inexperienced person might have lots of trouble by using a leaky feeder over a very weak colony of bees. I certainly should not use one in such a place; but without the wise words of caution given by the editor, some beginner might. I don't suppose it would be much trouble to wax the corners, but some might prefer the simpler plan of putting water in the feeder before using, and letting it soak. I filled one with water, and it leaked a little; but before long it soaked up so as to not leak a drop, and I have no doubt it would remain perfectly water-tight till allowed to dry out again. I think, however, I would always give feed to bees in the evening, and then the leakage would be cleaned up before morning. However, your suggestion is wise: Try the feeder with water, and don't use till it is water-tight.

You say, friend Root, that the bees "would be very likely to build combs between the feeder and the honey-board." Now, here you have me at a decided disadvantage. I generally know pretty well what I am talking about; but in the present case I must confess I don't, for I never used one of these feeders. As a general rule, I don't believe in speaking favorably of anything till I have given it a fair trial; but in the present case I felt pretty

sure of my ground without trial; and as some who were adopting the T super might want a supply of feeders, it seemed too bad to let them invest in something more expensive without telling at once about this.

The T super is $4\frac{1}{2}$ inches in depth. The end-pieces of the feeder are $4\frac{1}{2}$ inches in depth, and the thickness of the bottom ($\frac{1}{4}$ inch) added to this makes $4\frac{3}{4}$, thus making the feeder come within $\frac{1}{4}$ inch of the bottom of the super. Add to this $\frac{1}{4}$ inch the $\frac{1}{2}$ -inch bee-space of the honey-board and we have a $\frac{3}{4}$ -inch space between the feeder and the honey-board (not "nearly or quite an inch," friend Root). I think it will be decidedly better to have the feeder just $\frac{1}{4}$ inch deeper, and then we shall have just the bee-space between feeder and honey-board, and it hardly seems to me they would be more likely to build comb under the feeder than under a super of sections.

Now, having gladly admitted the justice of your criticisms so far, I come to your last, and I just won't agree to that. You say, "I would not think of using such a feeder unless an outside shell be placed over it and the super." I have fed pounds and pounds of feed in T supers, with no outside shell, using Simplicity feeders and 6-quart tin pans, which would allow the feed to come as near the outside as the feeders in question, and I have no recollection of ever having had any trouble. The feeding was done, too, at a time when robbers were bad. As already intimated, the feeding was generally done in the evening; and, besides, my T supers are made of $\frac{3}{4}$ -inch stuff. The square joints are also quite true and close, so a bee could make but little headway biting through. Don't think I never have any had cases of robbing. I believe my bees will go through as thick a board as anybody's when

they are fairly aroused. Perhaps I had better say something about

WHAT TO DO IN CASES OF ROBBING.

And here again I will trust to your watchful care to see that I do not lead astray the inexperienced, for I am inclined to believe that, in a large number of cases, the very best thing to do in a case of robbing is to do nothing. Have you not sometimes had it happen, that, the first thing you knew in the spring, a hive was robbed and not a drop of honey left—bees and all gone? And if you didn't find it out till after the mischief was all done, did you ever know any further harm to come of it?—any adjacent hives robbed in consequence? But if you found it out while the robbing was going on, and moved away the hive that was being robbed, or shut it up, very likely there was trouble all around. Now, the whole thing in a nutshell seems to be something like this: Bees are very precise in their knowledge of locality, and the exact spot where they have commenced robbing they will visit again; and when all the honey is gone from that spot or point of entrance (perhaps provided they have finished the honey themselves), they decide there is nothing further to be done, and no surrounding hive is attacked. But if the meddlesome bee-keeper removes the hive which they were robbing, they know they left honey in that hive, and go to hunting for it, and thus attack the surrounding hives. So if any thing bees are robbing be removed, let some comb with at least a little honey be put in a hive in exactly the same place, and adjoining hives will be safe. Of course, see that all entrances are contracted in spring.

Yesterday I found the bees were robbing a colony in a double hive. They had been at it so long that it was not worth while to try to save what little honey was left (otherwise I should have taken out *part*), and I let them entirely alone. To-day they have left it, and another colony in the same hive, using the same alighting-board, with its entrance 8½ inches distant, is left undisturbed, although its entrance was left 3½ inches wide.

Marengo, Ill., Apr. 20, 1887.

C. C. MILLER.

Now, friend M., while we agree almost exactly on pretty much all these subjects that come up, there is one place where I, too, just *won't* agree—that is, if I understand you fully, but perhaps I don't. Let me explain.

When bees have got into a notion of robbing in an apiary, unless great care is taken it will continue to grow worse and worse until finally robbing is so much the order of the day and the excitement of the hour that your whole apiary may be so much absorbed in it they won't even notice the apple-bloom and clover when they come. If you have not had any experience in such a state of affairs, I can tell you that I have. At such times a pan of broken combs, such as is left after transferring, would be the ruin of almost any colony, if simply placed in the upper story; and if there were cracks through which the bees could get a glimpse of it, and a sniff of the broken combs, it would make matters ever so much worse; and I have never found complete relief from this kind of work until I adopted the Simplicity bevels and the chaff hives. Flat boards, cleated in the best manner I could devise, would warp and let a sufficient number of robbers get their heads through

the crack to raise the cover a little, and then they would get their shoulders under, and, in a little time more, away goes the colony where the pan of sweets was placed, and with it a queen worth perhaps three or four dollars. I would stop promptly every sort of robbing the minute I discovered it, and I would do this to keep them from getting into this mischievous habit of robbing. I have had good strong colonies overpowered and used up by just putting a pan of broken combs in the upper story; and I have been through whole seasons where robbing was so constantly going on that it spoiled all the pleasure and pretty nearly all the profit of the whole apiary. Later, after I had learned by sad experience, and had provided myself with better hives, I have so managed that scarcely a case of robbing occurred from spring until fall; and when bees are so carefully managed that they do not discover there is any way to get stores except from the flowers, we may leave combs of honey standing around with considerable impunity, and no bad results follow. I have sometimes thought it would almost pay better to brimstone an apiary of bees, when they had got well educated up to the business of robbing, than to do any thing else with them. I suspect that localities have a great deal to do with this. I often hear visitors say that their bees gather stores enough to be slowly increasing in weight during all the summer months. This is by no means the case here. We have many weeks together, right in the summer time, when a colony placed on the scales shows a loss in weight day after day. Now, my advice to the rising generation of bee-keepers is, to keep such a sharp, vigilant eye on the apiary during all the warm weather, that the bees never get a going enough to discover that stealing is among the possibilities. It just now occurs to me, that the same rule applies not only to kicking and balky horses, but to the younger ones of the human family as well. A stitch in time saves nine, in all sorts of vice, among bees or men. I quite agree with you, that moving the hive away when it is almost used up makes matters, for the time being, a good deal worse; but I would adopt it as the lesser of two evils. When it is almost night it may do to let them go ahead sometimes until darkness winds it up.

THE SMITH FORCE-PUMP, FOR BRINGING DOWN SWARMS.

THE USES OF FORCE-PUMPS.

FOR several years back, force-pumps have been recommended for bringing down swarms while in the air. We have never tested them ourselves, for the simple reason that we do not allow swarming to any great extent. However, if we were situated as some are, there is no doubt it would be a good investment to have a pail of water and a Smith pump in the apiary, convenient for emergencies of this kind. It is said, that the bees are led to believe a shower is coming up while being sprayed.

Whether or not this be true, the wetting of the wings would certainly have some effect in disorganizing their flying apparatus; and it might induce them to return to the hive immediately, or cluster upon the nearest available object. In the engraving the apiarist is shown in the act of giving the bees a shower-bath with the Smith force-pump. Unfortunately, however, the artist has represented the bees as being clustered, and I can scarcely imagine what desired effect could be had from spraying the swarm after being clustered, unless the apiarist were afraid that the bees might leave the limb and immediately thereafter start for the woods. The spraying of the bees would

it would not be as convenient for spraying bees on a chase, the pail could be carried and set down beneath a large body of the flying bees. It is superior to the Whitman, in that it will send a larger stream to a greater distance.

Any of our readers who are desirous of testing this matter of the possibility and the utility of the force-pump in bringing down swarms can do so with the Smith pump, and yet not be at a very great expense in making the experiment. If it is not successful in operating on swarms, it certainly is a very convenient thing to have around for fires, washing windows, watering gardens, spraying currant-bushes with a liquid that

SPRAYING A SWARM WITH THE SMITH FORCE PUMP.

probably compel them to remain for a little while, or at least until he could make such arrangement that he could hive the bees. Ordinarily, however, I believe the idea is to wet the bees while flying, in order that they may be speedily induced to cluster. We have had reports of the Whitman pump being used for this purpose, and, if I am correct, swarms were induced to settle. The Whitman pump, however, costs more money than most apiarists care to invest in any thing that will be uncertain as to its utility in bringing down swarms. The Smith force-pump, at the present price of \$1.00 each, is within the reach of all: and while perhaps

is death to currant-worms, for cleaning out worms' nests in fruit-trees, and for renovating chicken-coops by spraying the inside with a thin solution of whitewash. In regard to cleaning out worms' nests in fruit-trees, I would say that this was one of my jobs when a small boy. With a force-pump and a pail of water I could blow the worms' nests to pieces in short meter, and it didn't matter how high above the ground, or how inconveniently the nest was situated, the pump would scatter the worms like a small charge of dynamite. It was only last summer that I had a patch of thrifty growing tomato-vines in the back yard. They were

located some 50 or 60 feet from the pump. In dry times we had to carry our water in pails from the pump to the vines—an operation that was rather long and tiresome. One evening the thought struck me to try the Smith force pump. I went over to the factory and got one and stood it in a pail of water right under the spout of the cistern-pump. The idea was a very happy one, for I could stand right there at the pump, single out each plant, and give it all the water it wanted, without moving a step. As fast as the pail was emptied I stood without moving a step, and turned the handle of the cistern-pump a few times, and the pail was full again. Now, if those tomatoes didn't grow, and if we didn't have nice tomatoes, it was no fault of the Smith pump. In the same way I have drawn up our buggy within a convenient distance of the cistern-pump, and with the Smith force-pump I could just deluge the thing without being obliged to put on overalls or any thing of the sort, until I was ready to sponge the buggy off.

After testing one or two of the cheaper grades of force-pumps, we have given our preference decidedly in favor of the Smith. It works very easy, in consideration of the large quantity of water it throws, and the distance it forces it. On this account, in case of fire we think the Smith would do better execution than the majority of higher-priced force pumps on the market. If any of you are desirous of knowing the height to which you can send a stream, I would say that, on several occasions, we have easily sent a pretty good-sized stream of water clear on top of our factory.

OUR TEN-CENT KNIFE FOR CUTTING UP SEED-POTATOES.

THE ONE, ALSO, RECOMMENDED FOR KITCHEN USE BY DR. MILLER.

BELOW we give you an engraving of the knife that has been mentioned by Mr. Terry and Dr. C. C. Miller for a kitchen-knife, and for a knife to cut up potatoes to plant. You will notice, that the handle projects in an odd sort of way up along the blade, to give a rest for the forefinger, spoken about on p. 258. The blade is the J. Russell & Co.'s finest steel—the same, in fact, that they use for our Novice honey-knife.

OUR TEN-CENT KITCHEN-KNIFE.

The special feature of this knife is in having the blade so thin that, when it passes through a potato or apple, there is scarcely any resistance. Then the keen sharp point is just the nicest thing that can be imagined, for cutting out the eyes or objectionable spots. It is also an excellent knife for paring and coring apples. We are enabled to furnish them at the low price mentioned, by buying them in great quantities. If wanted by mail, add 4 cts. extra for postage.

THE SPIDER AS AN ENEMY OF BEES.

A COUPLE OF INSTANCES IN POINT.

AT various times, writers in GLEANINGS have pronounced the spider a friend to the bee-keeper. It seems to me that this statement ought to be received with considerable allowance. A year ago I prepared a number of cases of sections, a considerable time before the honey-harvest began, and piled them on top of each other until I should need them on the hives. When placed in position at the proper time the bees promptly took possession of nearly all; but there were several very strong colonies that resisted every effort to force them into the sections. I reversed combs, uncapped honey, and contracted the hive space, but all to no purpose. It never occurred to me to see if any thing was wrong in the cases; but at the end of the season I found that each case was occupied by several large and exceedingly vigorous spiders. They had taken possession before the cases were given to the bees, and they held possession all summer at an expense of several dollars to me. I doubt very much if the most aggressive colonies would have the courage to displace such intruders.

But it is not at the hive alone that the spider is a nuisance to the bee-keeper. Several years ago I was amusing myself in the flower-garden one morning by pulling open the corollas of pinks that a bee had been vainly trying to enter. When it thrust its head into the narrow opening I would pull the petals apart so that it might reach the nectar at the bottom of the cup. At length the bee alighted upon a cluster of flowers on which was a small green spider not more than a quarter of an inch long. For a full minute the insects regarded each other without moving, then with a sudden spring the spider seemed to clasp the head of the bee for an instant with his anterior legs. In a moment he retreated to the further edge of the flower-cluster, and the bee rolled to the ground dead. Before the spider made his spring the bee seemed dazed and confused; and my wife, looking on, begged me to interfere for its protection. But I believed the bee was safe against the attacks of such a puny enemy, and I could hardly believe the evidence of my eyes when I held the dead bee in my hand. I can not think of the incident yet without a feeling of regret.

Who can tell how often these tragedies of the fields are enacted? The spider is everywhere; and if it is habitually so spiteful and venomous, it deserves to be ranked among the most destructive enemies of the bee. It is, undoubtedly, an excellent protector of empty combs, but beyond this I consider its usefulness to the apiarist as ended.

Denison, Iowa, Apr. 18, 1887.

Z. T. HAWK.

Friend H., the point you make is, no doubt, a most important one, and I should like to ask if others have had a like experience; and we want Prof. Cook to tell us, if he can, what spider it was that killed that bee, and by what means he did it. There are surely spiders enough at the college museum to include this very chap. If I am correct, spiders have no means of killing their enemies except by a mechanical operation; that is, they have no poison-bag nor poisonous spittle, neither is their bite poison-

ous. How, then, did this spider kill the bee so quickly? The bee is quite tenacious of life, as many of us have discovered when trying to kill an angry bee. I know a great many claim that spiders can bite, and that their bite is poisonous. Prof. Cook declares this is all fallacy and superstition, unless I am mistaken.

N. C. MITCHELL.

GOOD NEWS! HE HAS GIVEN UP SELLING FARM-RIGHTS, ETC.

OUR older readers will remember that, for a series of years, we were obliged to caution the public about sending money to friend Mitchell. For four or five years back, however, we have heard but little in regard to him; but within the past few months several friends have forwarded us his circular, with a drawing and description of the National Bee-house. We notice by this circular that Mr. Mitchell has discontinued selling rights—at least, the circular reads as follows:

We have no farm-rights to sell you now at any price, for the reason that, if we did so, not one of you in five hundred would know what to do with them, and you would be no better off than you now are with the hives that you already have in use.

This, certainly, is true, and, I believe, honest. It does us good to be able to find some point on which we can gladly shake hands with our old friend. He advertises a new honey-extractor, better and cheaper than any other in use, for \$2.00; also a new apparatus for making comb foundation ready for the bees; net cost, \$1.50. We suppose these things are to be sold to the members of the class which he organizes in each place; and if the customer receives the article as he hands over the money, we do not see that there can be very much fault found.

Now, I wanted to close this notice without finding any fault; but I feel really obliged to say to those who have had no experience with Mr. Mitchell, be sure and not pay him a cent of money for any thing that is to be shipped you or brought you some time in the future. Below is a letter forwarded to us by one of our subscribers. It was directed to Watertown, Washington Co., O.

To any Bee-keeper:—Will you kindly permit me to ask a few questions? I spent, last week, a day in Perry County, and was surprised to find your hilly country the greatest honey-producing county in Ohio. I will visit your county soon, with the view of finding a good location to start a large apiary. We want a location where fruit can be had in quantities at fair prices, and where blackberries and other wild fruit may be got in large quantity. We are now putting up fruit canned in honey. If you or any of your friends can give me the desired information you will confer a great favor upon us. I never knew until recently of your honey resources, or I would have been with you long ago. Address me at Columbus, O. N. C. MITCHELL.

Columbus, O., Apr. 7, 1887.

Canning fruit in honey is surely a laudable undertaking, and we wish our friend success

in the matter, even if he does teach his pupils by classes at a dollar each for a single lesson.

YOUNG CARP IN APRIL.

A LETTER FROM MILTON P. PEIRCE, EDITOR OF THE JOURNAL OF FISH CULTURE, ETC.

NOTICE your remarks under the above head in GLEANINGS for April 15th. I think you must certainly be mistaken about those tiny little fishes being carp, for those the size of a cucumber seed would ordinarily be but a few hours old, and surely there could not at that date have been any spawning—much less, hatching—for it is even yet too cold at this date (Apr. 20) for either. The conclusion forced upon me is, that they are some small variety of native pond-fishes. I have had many specimens sent to me by mail (dead, of course) for identification, but under the firm belief that they were our food-carp. They have always been tiny specimens of native brook or pond fishes. Had your date been one month later, I should not have thought that you had made a very common mistake.

In regard to sending carp in wet moss: I have several times tried the experiment, not only with moss, but with clean sponge and other apparently suitable material, but only with trifling success. I have, however, during the past winter sent 100 very fine-bred, parti-scale carp, in a peculiarly constructed tank, to the City of Mexico, a trifle over 3700 miles, and 95 of the 100 reached there alive and in good condition. Another shipment, sent this spring, from the same stock and in the same kind of tank, over the same route (as I suppose), certainly by the same express company, were all dead before they had crossed the State of Texas. I have for years expressed the opinion, that carp should not be shipped in the spring. Their vitality is at the lowest then; whereas, in the fall and early winter they are in the most hardy condition of any portion of the year.

I much regret, friend Root, that you, who have so excellent an opportunity to aid this promising industry, do not engage in it in a systematic manner. You have a very good site for the purpose, and ample facilities for a model establishment, such as would induce hundreds of others, not only in Ohio, but elsewhere, to start right, or remodel their present crude establishments. M. P. PEIRCE.

Philadelphia, Pa.

Thanks, friend P., and I am sorry to be obliged to admit that you are right about it, for I caught some of the minnies and found them to be little fish just like those in the creek. Now, can you tell us how in the world they got into our pond? It is so much above the water in the creek, that overflow is out of the question; and the only way in which I can account for it is, that the brook fish must have got in through the holes the musk-rats cut in the banks of the pond, letting the water out. I suppose the only remedy is to draw the pond dry and kill all these spurious fish. The reason I do not go into carp as you suggest, is such as is given in my reply to friend Terry, on strawberries. If Blue Eyes, Caddie, or even our four-year-old Huber, should get a fever for raising carp, then the way would be open.

ANOTHER WAY OF EMPTYING THE T SUPER.

WITH THE T TINS STATIONARY.

FRIEND ROOT:—I suppose, from what you have repeatedly stated, that you are often burdened with more correspondence than you desire or can make use of, and for that reason I have kept silent many times when I fairly ached to put in a word upon some current topic under discussion; and when I saw in GLEANINGS for April 1st the description of C. C. Miller's method of removing sections from surplus cases, I thought I would venture to give a brief account of my way of doing the same work; for you know that, when we have what we believe to be an extra good thing, it affords us pleasure to compare notes with our friends.

I use some surplus cases similar to those of friend Miller's, except that I fasten the tin T's permanently in their places. To get the sections out of the cases, as thus made, I have a bearing-board, with upright blocks $4\frac{1}{2}$ inches high fastened upon it, corresponding to each row of sections in the cases, and with spaces between the upright blocks to allow a passageway for the tin T's when the case is pressed downward. This bearing-board is placed in a machine made for this purpose; a case of sections is set upon it, there being stays on three sides of it to hold it squarely in its proper place; then by means of a treadle a follower is brought to bear upon the entire length of the opposite sides of the case, in such a manner as to force it downward evenly all around at the same time, the follower having guides which hold it firmly so that one side or corner can not get in advance of the other parts and twist the case out of shape, and thereby cramp and break the sections. If a steady gentle pressure does not separate the case from the sections, let up a little on the treadle. A spring lifts the follower upward, then a quick downward motion will give the necessary force to break any wax or propolis which may be holding them together, and the case will slip down out of the way. The sections will be left standing on the top of those upright pieces upon the bearing-board, ready to be removed. I also remove sections from the wide frames with this same machine, but have a different bearing-board.

Now, friend Root, for the sake of brevity I have not entered much into detail in the above, but have simply given an outline of my way of getting sections out of supers.

JOSHUA BULL.

Seymour, Wis., April 16, 1887.

Many thanks, friend B., for your suggestions. I have no doubt that the plan for emptying the T super with the T tin stationary will answer excellently. If I am correct, Mr. Heddon has a follower something similar to yours; but I believe you have improved it a little by means of the foot-power attachment. If with your attachment the super can be emptied of its contents as quickly and easily as friend Miller does it, I don't see but there would be considerable advantage in having the T tins stationary. I believe, however, there is another advantage, with the loose tins, the super can be filled easier. When you have a good thing, friend B., and fairly ached to let it out don't be afraid of the everlasting "waste-basket." We always try to arrange

it so that communications of general interest shall appear; but sometimes we are so flooded that even good articles have to be held over for some time.

OUR P. BENSON LETTER.

THE WINTER APERRY.

I PROPOZE to organize a winter aperry. It is well nigh that the most prophetable way to maik butter is the winter dary. Simmilarly likewise it's the same with bees. Summer aperrys is going out of stile, and winter aperrys will be all the go. The man which wants to maik munny at the bee bizness must git a winter aperry.

The advantiges of a winter aperry is too tejus to remunerate. But I will sho a phue points in which it is soupeeryer to summer. Jennerly winter izzent so hot as summer and yure apt to swet moar in summer and it makes the bees mad to see you swet.

Next, the winter aperry is not out door but in under shelter. This makes it suitful for dellykit ladies, which they doant like to spoil thair complekshens in the hot sun in summer.

Agane, evry buddy hed ot to keep a winter aperry on aekount of bekow all others keeps them in summer, tharefore the competishen will be less.

MY WINTER APERRY.

The winter aperry is constructed with (4) four walls and a dore and a glass roof. The roof is the grate feetyour of my winter aperry. It is egg-zackly opposit a house roof. Whair a house or a barn roof goes up the winter aperry goes down and visy-versy contrarywise, the hiest place in the roof of the winter aperry is jist whair the house roof is lo. The object of this will be quite a parent on a little refleekshun. It is to collect the rays of the sun, for the common roof maiks the rays of the sun slide off and the roof of the winter aperry ketches them. A sub-ventillater shaft starts (3) three feet above the ground and cums out at the roof to let out the rays of the sun when thay git too noomerous.

Sitch is the the prinsypull points of the winter aperry. The rest is eazy. Git my winter strane of bees, and feed them out of my youreeky feeder and thay will maik moar hunny than in summer, for you see the bees kant git out of the winter aperry and git lost like thay do when thay fly off in summer. Bees doant dy in summer; you ken see that by looking at a hive; thay jist fly off and git so far thay never git back.

I grate advantage of the winter aperry is that bees doant sting in winter. Hwo ever herd of bees attactin enny buddy in winter? So you see if evry I kep a winter aperry, it woud avoid the necessity of a law soot.

P. BENSON, A. B. S.

A. B. S. is fur Apiculturistical Bee Keepin Sigh-entist.

WINTERING BEES UP TOWARD THE NORTH POLE.

Without any Stores Whatever.

W. F. CLARKE'S HIBERNATION THEORY ESTABLISHED FINALLY ON A FIRM BASIS.

AS I happened to be down from the north to see a friend here in Ontario, I was reading your bee-paper. I noticed something in it about bees being frozen in the snow over night, and coming to life again, and your remarks as to how long and how low a temperature they would bear, and come back to life. I have found to my astonishment, that no one seems to understand how to winter bees without food and without much trouble, and with a certainty of having them all in the spring, and especially to have strong colonies in the spring, both in Canada and your country. I expected to learn something new and improved about keeping bees when I came down from the north; but, as I said, I was astonished to find I could learn nothing on wintering bees.

Where I came from is north of Nipising, about 150 miles from the arctic salt water; namely, James Bay, a wing of Hudson's Bay, in a great plain where bloom abounds for about two months. The honey-flow is great while it lasts. We get about 200 lbs. per colony; but if we wintered them the way you and others do, we could not get more than 25 lbs. of honey from each colony, because the bees would consume all, or nearly all, in the winter and non-productive months.

Now, for the good of your people as well as for Canadians, I will tell you how I manage mine; but I must be honest, and tell you it was not my own finding out. I learned it from an Indian who had never seen a white man until I straggled into his country. We became friends, and he told me his secret. I saw there was money in it, and went in with him. We have well nigh made a fortune. We got our honey down a tributary of the Ottawa, and paddled it down, and then returned in time to put our bees away, then hunted and trapped all winter. We generally had 25 Indians with canoes, with some small rafts attached, to take down our honey every fall, after the fourth year; but we never had much left when we got to Ottawa. We traded it to Indians for furs, on our way down, often doubling and trebling the price. As each canoe was unloaded we let it return, and so on. That was ten years ago.

You and your readers will perhaps wonder how I got there, how I came to stay there, and how I could talk to a wild Indian, and so on. Well, my story is easily told. I was crossed in love. I went north into the forest, with a gun and knife and dog. I fell among Indians, learned to talk their language, and, as I said, I straggled into this man's territory. He is a chief. I finally married his daughter, and we are a happy family all round, mother-in-law and all. We have five children, healthy and plump, and as nimble as otters. Well, to business.

The old man found the secret by accident. He fell a bee-tree late in October, and took the honey. The bees clustered under a hollow piece of wood, and there came a fall of snow that night. He went to see if he could find more honey next day. He looked at the bees, found they were numb, but would come to life when he warmed some in his hand. He conceived the idea that, if he would cov-

er them up in snow, they might keep that way till spring. Accordingly he covered them with bark, then with snow, so no frost could reach them. As soon as spring opened he went to them with a log hive he had prepared, dug them out, put them in, and carried them home. When they got warm, all but a very few began to crawl and finally to buzz. He fed them maple syrup that he had just made. They did well. We made our hives of elm bark, by peeling it in June. We had to employ help. We pressed it around a square block of wood, let it dry, then sewed one seam. We made all one size, so we could set one on top of another, each one a foot square inside, 14 inches deep. We use no foundation. We manage to get the top hive full of clear white comb. We take all of the best out of the bottom; but how do the bees live over winter, with no honey after the middle of October? Well, they don't live—at least, they eat no stores. Here is the way we do it:

The first cold nights we uncover the hives so they will get perfectly cold through, then keep them in a cool place in the shade, with covers on loose, so as to keep them dry. As soon as there comes a good fall of snow, which always comes there before hard frost, we have a cave into which we pack a lot of snow, then lay dry bark on it, then the hives, then cover with dry bark, then pack about two feet of snow over them, shut all up, and cover all over nicely with snow. We never look at them till about the first of May; but if there comes a thaw we are careful not to let any wet get down. We do this by packing more snow on, and cover with green hemlock brush, so as to keep the sun off the snow. When it begins to thaw rapidly, and spring is upon us, we dig the bees out, set them in the sun with covers off; and if it is a fine warm day we have them humming in a few hours. We cover them at night, uncover them next day, and cover at night again for the last time. Our bees are all in full blast in three days, carrying in pollen. The hives are in full strength—no sickly hives, no spring dwindling. By the first of June we have on the top hives. The only danger in putting up bees for winter our way is, if there are any hives with the least warmth left in them the bees will come to life, then smother, or starve—at any rate, die they must, and be worthless. We never lost more than two hives in that way in eight years. I now think you can all understand the cold plan of wintering bees. I suppose it would be more difficult where the winter is not cold enough. If you or any other bee-man would like to communicate with me or my father-in-law and partner, Eagle Muskegoon, about our bee-business and management, he can do so, and can reach us by writing to my friend George Watson, Alliston, Ontario, who has a way of communicating with us. He keeps bees, and intends to try our plan next winter. He has lost most of his bees this winter already, and there is another month before they can fly here yet. There is good sleighing here now, and nearly as cold as January.

This was written for me at my request, and for the good of my fellow-men, or as many as it may concern. My letter is long, but I should like to tell you something about the effect of honey by its use with Indians. The three youngest of my father-in-law's children, who were born at and after the time he began to have plenty of honey, are of much better complexion than the others. My children are soft, clean, and bright-skinned—a kind of "English

cream-color." My wife has noticeably improved in complexion too, and I verily believe all this came from the liberal use of honey as a diet; but it is not only in the ones I have mentioned that the effect is noticeable, but in several other families as well; and from those facts I have not the least doubt but that if white people, especially those who are dark, or troubled with pimples on their face, would use honey liberally, it would improve their color and give them a clean, smooth skin. It would be much better for young ladies than all the potions, washes, and sham drugged stuff they are eternally buying to beautify themselves.

I am, sir, yours in bee-love,—DANIEL MCFADDEN.

I am sure, dear friend, we are very much obliged for your kind letter; but we should have been better pleased to have had your address in full, or at least your *nearest* post-office, if there are no mail facilities near you. As it is, we hope to hear more about this wonderful experiment, through your friend George Watson. Bees have over and over again been wintered with so small an amount of stores that more than one of the bee-friends have been almost persuaded that the bees could live for months, as you state it, without any food at all; but yet all experiments made directly to prove this have somehow failed, and most of us have settled down to the belief with Prof. Cook, that bees do not hibernate. Perhaps in a climate like yours it is possible to secure a cave with a constant temperature a little below the freezing-point; and although it seems to us now that there must be some mistake somewhere, and that your bees had just a little stores when they started in their long winter, we are open to conviction, and I have to-day directed a letter to George Watson, asking him what he can tell us about you and your strange communication.

THE T SUPER.

WHAT SHALL BE USED TO SPACE OUT THE TOPS OF THE SECTIONS?

FRIEND ROOT:—GLEANINGS seems to be largely occupied with the T super lately—perhaps more so than some may desire; but I always like to see a thing discussed in a way that will bring many minds to bear upon it. I believe that our bee-periodicals have done more good by taking up a subject and discussing it thoroughly than they have in any other way. Of course, there is a time when such discussion becomes mere repetition, and then it is time to turn into some other channel. This is my excuse for presuming to write any thing more about the T super, for I do not think the subject is yet entirely exhausted.

First, I wish to say that my experience with 25 of them, for two seasons, has been such as to corroborate almost every thing that Dr. Miller has said. I wish to dwell upon a few points that he suggests on page 247, in his review of my former article.

The supers that I have been using are just the least scant 17½ inches in length, inside measure. They are too short. They can be used, but they are too difficult to fill with sections, as the sections strike upon the tops of the T's. I have made one

17½ inches long, and filled it with sections, to see how it would work. I think this is just about right. I feel very sure that any one who makes them shorter than this will regret it, also that there is no necessity for making them longer. But this length leaves a space between the rows of sections that I never could be contented with; there must be some way of filling it. I tried the T tins on top, with two or three supers, last summer. It accomplished one thing perfectly—it holds the sections square; but it is objectionable, because of the lines of glue that are placed where the tins meet the tops of the sections—right where we want our sections the cleanest. Also because it necessitates a special T tin, or a separator less than 3½ inches wide, or the reduction of the tins to less than ¾ inch in depth; for to try to use a T tin on top that figures say will just touch the separators below, will never do. I do not like either one of these three choices.

Dr. Miller also suggests that, in place of a T tin on top, merely a straight piece of sheet iron or heavy tin be used of the proper length, and of a width so it will rest on the separators and come just to the tops of the sections. This holds the sections square, and prevents the gluing. If heavy tin is used, let it be ever so heavy and it is too frail. It will always be getting bent and kinked out of shape.

The sheet iron may do, but I think I know of a plan better than either. Take a piece of tin of the right length and width, and bend so the end will look like this . This makes a bar stiff enough so, with any fair treatment, it will not get bent out of shape; it is also folded so that it is the same thickness as the T tins are below it, and both edges are rounded, making it nicer to handle and easier to insert between the rows of sections. What can you furnish them at, friend Root?

Now about the size of the T tins. Dr. Miller's are ½ inch deep, and, as I understand it, you are making them so. Mine are only ⅜; and if they were only one-half as strong as they are they would be just as good. Now, if they are made only ⅜ they let the separators down where I think they belong. My separators are 3½ inches wide, but I rather think, as Mr. Heddon said in March 15th GLEANINGS, that 3¾ would be better.

WINTERING.

I winter in the cellar. Winter before last I gave upward ventilation by slightly raising the cover, which is merely a cleated board lying on the hive. Bees came out weak. Last winter I left the covers glued down tight. Bees seem to be in good condition this spring—all alive. They were somewhat stronger last fall, however, than the year before.

Iowa City, Iowa, Apr. 9, 1887.

WM. DREW.

Thanks for your suggestions, friend D. For the inside length of the T super, 17½ is about as near right as we can get it. We have made all ours that way, and, so far, I believe we are on common ground; but we are not so decided as to what would be the proper width of the T super. Dr. Miller has the inside width of his super exactly 12 inches. Ours is 13½. The supports on our T tins are ¾ inch high. If they were ½ inch high we could not, of course, use separators 3½ in. wide, with another T tin on top. For those who may prefer to use the T tins above, we decided upon the height of ¾ of

an inch, and we believe there is no disadvantage in changing from $\frac{1}{4}$ to $\frac{3}{8}$ of an inch. The point you mention, that, when the T tins are used on top, the bees propolize along the edges of the T's, has been suggested by others. Our friend Mr. M. G. Chase, of Whittlesey, Medina Co., O., uses only such comb-guides as are used in the Simplicity frames. These comb-guides he cuts off the proper length, and drops them down on the separators between the sections. We believe that the folded tins you speak of are better for the purpose. We can furnish them $\frac{3}{8}$ of an inch wide for 60 cents per 100; postage, 60 cents.

DRONE COMB.

WHEN AND UNDER WHAT CONDITIONS THE BEES BUILD DRONE AND WORKER COMB IN THE SOUTH.

WHEN reading Mr. W. Z. Hutchinson's article on drone comb, Dec. 15, 1886, page 969, I was very much struck with the points he made in the article, in reference to bees rearing drones, and the building of drone comb. The experience that he gives is very much different from mine on a few particular points.

He says: "Many have reported that their newly hived swarms built drone combs when the queens were *not* old. True; but, look'e here; they didn't raise any drones." Yes, sir! at least, if they didn't I have had them do so. It is seldom the case I can have a swarm on empty frames, even when the queen is less than one year old, but that it will build at least as much as one full L. frame of drone comb in 8, and rear drones, and keep them, too, till fall. I seldom ever have a hive of Italian bees that kill out their drones before September. Few drones are kept by black bees after June 20th, although they rear them, the same as the Italians do, throughout the entire spring and summer. Mr. Hutchinson also says, that bees build drone comb to store surplus in, when they are storing it rapidly. He says: "And they can store it faster by building store or drone comb than they can by building worker comb." I think myself that they can do it, but certain it is that they *don't* do it here in our climate, when they are storing honey rapidly, but invariably build *worker* comb when honey is coming in fast. As soon as the honey-flow is pretty well over in the spring, with very little surplus being stored in the sections, the bees begin to build all their comb in the sections of drone comb. They build but little else the rest of the reason, unless we happen to have another pretty heavy honey-flow. In the event that we do, the bees at once resume the building of worker combs in the sections, to store their surplus in.

I can nearly always tell at a glance, when I open a hive, whether honey is coming in fast or slowly by the kind of comb the bees are drawing out in the sections. When they have a section 6 inches square, built half down in drone comb, and honey begins to come in freely, they at once change and finish out such sections in worker comb. Now, why is this, unless it is to economize in the production of wax? Then, again, why such a difference in our bees in building combs? Certainly it must be due to the difference in climate.

If, then, these differences are due to climate we should always, in reading after various writers, especially when there is a very radical difference in their experiences, take into consideration the difference in climate as well as other conditions.

I transfer bees from box hives into movable-frame hives, comb and all, such as is suitable to use again, for my neighbors, at 50 cts. per colony. All are black bees, of course. I have transferred 15 and 20 hives at a place; and many, sometimes half, the number of hives, would be half drone comb throughout the entire hive. A. L. SWINSON.

Goldsboro, Wayne Co., N. C., Feb. 7, 1887.

Friend S., my experience indicates that drone comb is built when honey is coming in the fastest, and I supposed it was for the reason you give, only it seems to me it is the drone comb that takes the least wax and the least labor, while worker comb takes the most wax and the most labor. I agree with you, that some colonies fill worker comb, even during a heavy flow, while others change over to drone comb where they had commenced starting worker; and they build this drone comb, it seems to me, with much greater rapidity than they could possibly spin out the worker comb. I have also noticed, that when an old colony was preparing to swarm they would fill an empty frame with drone comb with almost incredible rapidity. In this case the comb would not be very nice or very true; but it often has the look of being gotten up with very little care or attention.

AN EXPEDITIOUS WAY OF REMOVING PROPOLIS.

HOW TO HAVE CLEAN HANDS AND CLEAN CLOTHES.

PERHAPS some of your readers would like to know of a convenient and cheap way to remove bee-glue from the hands. With me it is cheaper and better than alcohol, ammonia, or any thing else I have tried. I have some slacked lime handy where I wash my hands. After wetting them I take some of the lime and rub them thoroughly with it, re-wetting them and using more lime if necessary. Thin whitewash does even better. When washed off, a little vinegar will make the hands feel natural again. As my business is "looking down in the mouth," as it is said of dentists, it is quite an item with me in bee-keeping to be able to get my hands in a presentable condition on short notice, when some one calls to have dentistry done.

The plan above has been satisfactory with me for the last eleven years; but week before last I found, or rather Mrs. Mason suggested, something that proved to be better. It "used to be," that, when I got any propolis on my white shirt or "brichaloon," she would give me a little talk for being so careless; but it would get on in spite of all the talking she could do. She doesn't talk to me any more about it now, and it is such a relief! Two or three years ago she came across a recipe for a first-class washing-fluid, and she won't wash without it. Some of our neighbor women are just as notional about it as she is; and if all of the lady readers of GLEANINGS who have to wash, not dirty *men's* clothes but *men's dirty* clothes, will try it I don't

believe they will want to get along without it unless they have something better.

Here is the recipe: One pound crystal potash; one ounce strongest aqua ammonia; one ounce borax, and one gallon of soft water. Put all in a jug and keep well corked. Use half to two-thirds of a cupful, and about one inch shaved off an ordinary bar of soap, to a boiler of clothes. Soak the clothes over night; wring them out in the morning, and boil without rubbing; rinse thoroughly and you will be delighted to see how white the wash will be. Mrs. M. uses soft soap, and uses the fluid in soaking the clothes also, and rubs the dirty spots.

Week before last, one warm pleasant day I set some of my bees out of the cellar for a flight; and in looking over some of the colonies I got my hands more than usually daubed with propolis, and then, of course, a lady had to call to have some teeth filled. My hands were in a pretty fix. It being winter, there was no lime at hand; and alcohol, ammonia, benzine, turpentine, and coal oil were too slow coaches, in my hurry. My better half came, as usual, to my relief by suggesting that I try the washing-fluid. She poured two or three tablespoonfuls in the wash-dish, and I "showed my faith by my works." My! but that propolis was awfully scared, I verily believe, for it left my hands almost instantly, and they felt as though the skin might be wanting to keep it company; but some vinegar stopped such a proceeding, and I had some clean hands. The memory of the oldest inhabitant at our house doesn't reach back to the time when they were made so clean in so short a time. I shall use the washing-fluid to remove propolis in the future; but unless I forget it, it will be diluted some before my hands get into it. It may not come amiss, although not new to many, to say that, when the roughness of our hands gets filled with dirt that soap and water don't remove, we put twenty or thirty drops of aqua ammonia, more or less, in a wash-dish and add two or three tablespoonfuls of soft water, and wash the hands with it. It is pleasing to see the dirt unite with the water and ammonia so quickly.

Mrs. M. wishes me to say that she thinks "Mr. Root must have taken pains to select a nice "Go-shen" carpet-sweeper when you sent ours, it is so nice and works so nicely. I don't like to tell her that I don't believe you even know that we ordered one of you, and then she won't know but you did her a most special favor. It was her valentine, but I call it her little wagon, and it is nice and handy to have in the house. A. B. MASON.

Auburndale, O., Mar. 19, 1887.

Why, friend M., you started out to tell us how to remove propolis, and have indirectly given us a valuable preparation for washing clothes, and the latter is probably of a hundred fold more moment than the former; but I watched anxiously to see some remark in regard to injury to the clothing. Mrs. Root used almost the same thing years ago, but finally abandoned it, because she and others thought it made the clothes wear out faster. Will your good wife please tell us her opinion in regard to this point? In any event, the recipe would be an excellent one for bee-keepers, I am sure. When I was in the jewelry business we used to have a large bottle of ammonia on a shelf over the sink, and the hands were so much in the

habit of using it when washing grease and other accumulations from their hands that it got to be an expensive item. It is an excellent thing to have in the house, at all events, and perhaps the friends remember we have had it put up in bottles on our 10-cent counter; in fact, it is there especially advertised for removing propolis, with the addition of a little soap. Now, are you sure the potash and borax make it any more effective?—Many thanks for Mrs. Mason's kind opinion of the carpet-sweepers, and of our establishment in general.

HOUSE-WARMING.

HONEY-BOARDS, AND MENDING TINWARE.

NOT one-half the people whom GLEANINGS reaches think they are able to have a furnace or a hard-coal base-burner, or keep up fires in stoves so as to warm distant bedrooms. I think it would be cheaper in the long run, as it would save taking colds, I am sure. The next best thing to having rooms warmed is soapstone foot-stoves, one or more of which will last for a lifetime. They take heat quickly and hold the heat a long time. We find it a great comfort to have one heated and laid in bed, where our shoulders come, and at night push it down to our feet. We find them much more comfortable than a jug of hot water, an iron, or a brick. The soapstone seems to hold the heat longer, and need not be heated scorching or sissing hot.

HOW TO MEND TINWARE.

Not long since I learned how to solder. It seems a simpler process than yours. I will give it to you and your readers. Procure a 25-cent bar of tinner's solder, and melt it up in an old dripping-pan, one end of which has two holes or more in it. When melted tip the pan so that the melted metal will run toward the holes. Let it run through them upon a long board or hard-wood floor; pull the pan slowly so as to make the solder come out in long slim bars. Cut up in lengths of six inches or so. Purchase 5 cents' worth of muriatic acid. Scrape the tin with an old jack-knife; if rusty, apply with cork a little of the acid; if not rusty, no acid is needed. Now light a candle or lamp. If a lamp is used, turn up the cap which is over the burner; leave off the chimney. Now hold the hole in the pan to be mended, over the flame, and with a bar of solder rub around the hole. The flame will melt enough solder to fill the hole in a moment, and the work is done. In this way I keep all my pans and cups mended. It is less trouble than to send to a tinner's, and less trouble than to be pulling in strings to fill the holes. Apply the solder to the side of the pan that is the least rusty. It is better to mend before the holes get too large, as it is more easily done. Practice first on the small holes, and then on the larger.

THE HONEY-BOARD WITH A BEE-SPACE ON TOP, AND A BEE-SPACE BELOW.

I am very much interested in the correspondence between Dr. Miller, Ernest, and yourself, in respect to the section-cases. I wish we could come upon something we were entirely suited with, and which needs no change. The honey-board with a bee-space below it and above the sections, I think, invaluable, as bees build bridges all over the tops of

the sections to raise up the cloths if cloths are laid over them. Last summer and summer before, as we had a great many division-boards cleated on one side, we used them on top of the surplus case, laying a thin quilt above to cover the sides, as the board was not wide enough. I mention this as there are a great many poor people who are keeping bees who feel they can not afford to buy all the new improvements until fully indorsed by others.

Roseville, Ill.

Mrs. L. C. AXTELL.

Thanks, Mrs. A. Your arrangement for mending tinware is much the same as the one we describe in the A B C book.

A CHEAP WAGON-BED.

HOW TO MAKE ONE FOR HAULING BEES, AND AT SMALL COST.

AS this is the time of year when some wish to move their bees to different locations, and get them ready for the season's work, I will give you a description of a cheap arrangement of my own that is the completest thing for its cost that I know of.

Now, a spring-wagon, made expressly for hauling bees, must be strong, and, of course, it will cost more than a great many will care to pay; so, instead of it, I made a bed 20 feet long and 45 inches wide, inside measurement. Under this are three heavy springs, so arranged that the bed can be put on any ordinary lumber wagon, and will carry all a team can draw. In the first place, I used two pine scantling, 2x8 inches, 20 feet long. These are the sides of the bed, and give it its firmness. Under these scantling, in front, is an oak plank, 1 foot wide and 49 inches long, placed crosswise, and securely bolted with 10-inch bolts to them. Under this plank the front spring is fastened with clips, and under the spring is a short false bolster, 2 feet long, clipped to it, and a king-bolt in the bolster, stationary. In putting the bed on the front axle, the bolster belonging to the wagon is taken off, and the false bolster, with its king-bolt, is used instead. Over the hind bolster, the same size of plank is used, and two springs are set crosswise, just inside the bolster-stakes. Two holes are made in the plank for the stakes to play through, as the bed springs up and down. The hind springs are set right on the bolster, and fastened to it with clips that can be put on or taken off at pleasure. For clips, $\frac{3}{4}$ -inch bolts are used with small yokes, 8 bolts to a spring; and for the clips around the hind bolster I put 4 bolts through small blocks of wood.

Now as to the springs: The front one is 6-leaved, 1 $\frac{3}{4}$ inches wide. The two hind ones are 5-leaved, and same width. They are 13 feet apart. The hind ones are five feet from one end of the bed, and front one two feet. A reach must be used with the wagon, of the right length, and it must be very firm.

As to the bottom of the bed, it is readily seen that the planks to which the springs are fastened will be a part of the support; and for the rest, place strips 2x2, and 49 inches long, crosswise, 2 feet apart, more or less, under the scantling, and fasten them with wood screws 6 or 7 inches long. We now have a frame for the bottom, and the bottom can be put on either movable or stationary. The rest of the bed can be finished according to any one's own inclinations. To summarize, we have the scantling for sides; planks and strips with boards on them

for bottom. It can be easily made; and, if made right, it will carry all the springs will bear, either 30 or 35 hives of bees, or a small picnic party, and it will cost about \$12.00 or \$15.00.

ROLAND SHERBURNE.

Lone Tree, Iowa, Apr. 6, 1887.

DOES THE QUEEN HAVE ANY THING TO DO WITH RULING THE COLONY?

PROF. COOK REPLIES TO FRIEND DADANT IN REGARD TO THE MATTER.

EDITOR GLEANINGS:—In the April *Apiculturist*, I write as follows: "Of course, we might speculate as one of our leading American bee-keepers has lately done in a leading bee-paper, in reference to the queen's compelling the workers to make drone comb; but in these days of scientific accuracy, speculation or mere theorizing goes for naught." A kind letter from our friend Dadant, who was the writer referred to (see article in current volume of GLEANINGS, p. 129), refers to this as ridicule, and asks me to explain why I see fit to condemn the theory. He rightly says, that theories have often done great good and have led to the greatest discoveries. He asks me to send my reasons for doubting his theory, to GLEANINGS.

First, I wish to disclaim all thought of ridicule. I look on Mr. Dadant and his son as among our ablest bee-keepers and best writers; and I never skip their articles when hurrying through our numerous bee-papers—so numerous that one has to pass some of them, or else pass much in all, if he does any thing else. Again, I consider Mr. Dadant as one of the broadest and most far-seeing of our American apiarists, and so one of our safest advisers. I feel to reverence such men who have grown venerable in a pursuit, and have left valuable finger-marks on every page. So hearty was my respect and admiration, that, when Mr. Langstroth asked me whom I would recommend to revise his great work, I at once suggested Chas. Dadant and son. I hardly need say, then, that I had no intent to ridicule.

I must say, however, that I was surprised at this article. The facts are certainly well established; but the reasoning and theory to account for them are not, to my mind, either sustained or probable. It was an idea in the olden time, that the queen exercised "sovereign authority." I commenced bee-keeping about twenty years ago, with this view. I soon became convinced that it was an error, and I have never seen any reason to return to the old views. It is true, as we all know, that, so long as the queen keeps the empty cells filled in the brood-nest, so long will only worker comb be built. Messrs. Dadant, Doolittle, and Hutchinson have given us excellent observations in this realm; and so long as they confine themselves to these facts, and the practical suggestions like that with which Mr. Dadant closes his excellent article, we are all profited; but the theorizing we had better leave, as did the great Charles Darwin, till we get such a wealth of fact and example that the theory may hardly be called mere hypothesis.

Mr. Dadant urges that the queen rules the workers in this matter. I have never seen a single indication that the queen rules the workers in any

respect, nor do I believe that she does. From my observation, it would be rather seem that *pro bono publico* is the motto of the hive. When honey is in excess, store-room is necessary; and it can be most rapidly fashioned if drone comb is built. I believe in this drone-comb building at such times, as also when drones are needed, as the colonies become crowded, and again when only storage is required, as in the absence of a queen; then all the bees cheer the work of building drone comb. Economy calls for this, and bees are excellent economists. When, on the other hand, bees are needed, and room for worker eggs imperative, then I believe all are in hearty accord, and are eager to see worker comb. It has seemed to me that Tennyson's lines state the law that governs in this bee-hive kingdom: "The individual withers, but the race is more and more." Let a bee become weighted with milk-weed pollen, stupid with age, or impotent from any cause, and how heartlessly the other bees drag it from the hive. I believe a queen is no exception.

The survival of the fittest, and the extermination of the weak, seems to be Nature's inexorable law. Even among men this law is not entirely absent. It seems to me that Christ introduced a grand improvement on this law; that is, kindness and love, even to the weak among us—even to our enemies. The bees have no higher ethics than the greatest good to the greatest number—no asylums, no almshouses there; yet so long as all are strong and able, just so long are all respectable in the bee-hive world, and each does its proper work with no let, hindrance, or compulsion. This is the impression which I have received from the closest observation I have been able to make.

WINTERING.

The spring may not be the time to write of wintering; yet it is the time when we are forming judgments that will control our future management. It seems to me that the question is solved; and that for localities in the latitude of Michigan, and, I think I may say, of Ohio and north, the cellar is the place. Give me a good cellar, and good honey or syrup in sufficient quantities, and I will warrant even rather small colonies. I speak after several years of absolute success. The cellar must be kept as near 45° F. as possible. Ours never falls below 38°, rarely below 43° F. This temperature may be cheaply and safely secured, either by sub-earth ventilation or by the presence of water. Probably artificial heat may be depended upon, but the above means I consider safest. The food must be good and abundant. Thirty pounds is none too much. It is very essential to pay close heed, after the bees are prepared for winter, that they be not robbed in the fall, and so starve during the winter. We lost one colony in this way a year ago, and two this winter. Every drop of honey was gone. Our apiary is so that we can not watch it continually, and so weak colonies, such as we form in autumn from nuclei, are, of course, subject to robbers. Our bees were in the cellar from November 12th to April 8th, and came out very strong. As in previous years, there is almost no brood. I prefer to have none. The colonies wintered in the new Heddon hives are wonderfully strong—I think because of the fact of a deep space under the hive. I believe that having the upper case full of honey, and the lower empty, would make a superb hive for cellar wintering. I wish all my hives were raised

one inch from the bottom-board in winter. I would cover closely above, but leave the entrance widely open. Bees wintered thus in a good cellar will give no trouble in spring, even though not packed. I know this because I have tried it. I wish to confine the bees on a few frames, and can succeed as well with single-walled hives as with chaff hives. I am not even sure that it is necessary to have packing above. A simple board may serve as well, but I am not sure of this. I shall try 25 colonies this spring.

Now, why I prefer the cellar is this: If the cellar is right, we are always safe, providing we look out for food. With chaff hives, we are not safe; at least, it so seems to me, even in the latitude of Central Ohio. Occasionally a long severe uninterrupted winter comes, and the bees are swept away, when those in the cellar are as safe as ever. Of course, the cellar *must* be right, but that can be secured with ease and certainty.

EFFECT OF BEE-STINGS.

I have noticed several references of late in GLEANINGS to bee-stings. This matter of bee-poison is surely one of much interest. In the many years which I have taught bee-keeping here, I have had often thirty or forty students a year. I always say to the class, that I do not think any one has properly completed the course who has not received at least one sting. Usually, each one passes satisfactorily in this respect. Of all these many students, only three have been seriously injured. In each of these cases, a severe fever was induced, attended with general swelling, even of parts distant from the wound, intolerable itching, and a sense of suffocation. I have always recommended cold water, either as a bath or pack, and it has always given quick relief; though the unpleasant symptoms of swelling and sore muscles would not disappear for two or three days. Very many are stung, and often there is considerable local swelling. For this we have tried all the remedies we have ever read of, from watch-key, clay, ice-water, to alkaline washes. We have not tried the new English remedy, but shall this season. Of all remedies, we have found ammonia the best.

The other day, in removing our bees from the cellar, we had a strange case. The student who aids me most with the bees has had, for several years, considerable experience in handling them. Like all who work with bees, he received the occasional stings, but suffered so slightly that he hardly noticed the matter, and cared scarcely any thing for it. Upon this occasion he was stung on the temples. In a few moments his skin all over the body was so red as to resemble a rash. Soon white blotches appeared all over his body. He felt faint, and seemed troubled for breath. I was somewhat alarmed. He went to his room at once, took a cold-water bath, and in two hours was relieved. He has been stung since, with no serious or peculiar effects. It would seem as if this was a case where the sting entered an artery or arteriole, and so the amount of virus injected into the blood was very great.

A. J. COOK.

Agricultural College, Mich., Apr. 12, 1887.

Friend Cook, in regard to the queen's ruling or leading the colony, permit me to call your attention to one fact laid down in the A B C book. In my early experiments I gave a neighbor a black queen that I did not want, to start an observatory hive. I

furnished the queen, and he furnished young bees by drumming them out of a colony of his own. In the course of two or three days the queen came out of the observatory hive, and all the bees followed her. She then came straight to our apiary and entered the hive from which I had removed her. Her own bees accepted her at once, but they stung to death the small swarm of young workers she brought with her. In that case they certainly followed the queen, or, at least, after they had all swarmed out together the queen led them to her old home.—It seems to me, friend Cook, you are just a little hasty in saying you consider the wintering problem solved; and I think, too, you do not give the chaff hive proper credit. We have wintered now from 100 to 200 colonies for quite a number of years, and the loss has been so light we almost feel, as you do, that there is no real need of losing bees at all, where they are properly put up for winter. Yes, we too winter weak colonies now without any loss at all, or, at least, we have during the past winter. I should be glad to think that we have the upper hand of this trouble which was, but a few years ago, such a grievous one; but it now seems to me we had better be slow in deciding that we are clear out of the woods.—I am a little surprised to see you decide that ammonia or any thing else has any effect in relieving the pain of a bee-sting. Have you tested first ammonia, and then nothing at all, a sufficient number of times to be sure it produces any effect whatever? Perhaps our agricultural colleges are the very places to have this matter settled; but if you set some of the boys at it and let them give it the same fair tests that they give artificial fertilizers, etc., I feel quite certain that the result will show the ammonia has no effect whatever on the bee-sting. The cold-water bath is, of course, a remedy for the symptoms you mention, but we have discussed this matter pretty thoroughly. The point is, Is there any thing under the sun that you can carry around in a bottle, that will give any relief whatever by applying it externally to the part stung?

LOW PRICES FOR HONEY.

CAN HONEY BE SOLD AT A REASONABLE COMPENSATION?

OF late a good deal has been said in the bee-journals about "overproduction, and the low price of honey." Although my experience has been limited, I have carefully studied the various points presented, and have been very much interested in all that I have read. The question has been handled by abler ones than I; yet many times things are brought out by the lesser lights that are obscured by the greater ones. I take the ground, that there can never be an overproduction of honey until the masses of the people of the country become consumers; but, how is this to be brought about? A small per cent of the people of this country are consumers of honey, and why? Because it is not brought within their reach. This can never be done by sending our honey to the great centers. We

must develop a home market. But some will say that there are so many going into the business, and who make a failure, they injure the business. This point is not well taken; for wherever bee-keeping has been attempted, and the people became accustomed to the use of honey, and bee-keeping failed, those who were the successful ones found a ready market for their honey whenever they put it within their reach. This was my experience when I located in Indiana. I was six miles from Ligonier. When I went there, most of the farmers kept a few bees and were accustomed to the free use of honey; but the various casualties destroyed nearly all the bees, and but few keep them now. I was successful with mine, and many of my best customers were farmers who formerly kept bees. I have sold as much as 100 lbs. to a single person. I created a home reputation and market for my honey, which I have never been able to supply; and the result has been that a good deal has been imported from a distance.

The last two seasons, I am aware that there are many producers who have a large amount of honey which they can not dispose of in their own immediate vicinity; but if they will take a load of honey, and canvass the country through, introduce it to the farmers, make arrangements to supply future demands, visit the towns around, introduce it to the people, and leave some on commission with one or more good men, they will invariably create a permanent market. It is true, this is accompanied with expense; but when once established it will not amount to as much as the delays, shrinkage, etc., met in sending to the large markets; and by withholding shipments to the large cities, and thus reducing their supply, better prices would be obtained there. I do not claim that the large producers can dispose of all their crop in this way, but they may greatly extend their markets and obtain better results.

Then, again, they must get their honey in the shape demanded by their markets, and not try to bend the markets to their style or notion. I think that Mrs. Chaddock has hit upon a sensible plan in GLEANINGS for 1886, page 887, in accommodating herself to the demands of her customers, and no doubt she will sell more honey in that way than if she insisted upon her style. I think with her, that there is too much style put on our honey for the general market. Let us put on all the style we can with our honey to tickle the fancy of the rich, and get as large a price as we can for it; but let us drop all the style we can for the general market, and try to get our honey as cheap as we can, to bring it within the reach of all.

That honey can be produced and sold with a reasonable compensation for money and labor invested, at a much lower figure than the present prices obtained, is fully demonstrated by many reports that have been published. A very great hindrance in accomplishing this end lies in the tendency of the people to abandon the cheap and simple hives and fixtures, and to experiment with and adopt many so-called improved hives, against which I have not a word to say, for they are all nice and convenient to handle, and to talk and write about; but any one will acknowledge that they are accompanied with more expense and labor, which I do not think is compensated for by the increased amount of production. What we want is a simple, inexpensive hive, with few parts, and all

appliances alike, so as to simplify the working of them as much as possible. All hives, frames, cases, and sections, necessary for the season's use, should be prepared ready for use before the season begins. A great reduction in the cost of production may be made by a proper and economical arrangement of the apiary, and its appliances to simplify the work to be done. A. D. STOCKING.

THE NEW BOOK.

A REVIEW BY R. L. TAYLOR.

A NEW work on "The Production of Comb Honey," by W. Z. Hutchinson, has lately issued from the press; and, coming as it does from the pen of one who has had so much experience in apicultural matters as Mr. Hutchinson, and who has made this branch of the business a special study, it deserves more than a passing notice.

In make-up and typography the work is above criticism; and coming in covers made appropriately in close imitation of bright comb foundation makes it altogether tasteful and unique in appearance. In style it is concise, lucid, and to the point. One determined to find a point to criticise might complain at the redundancy of italics; and perhaps the discussion might, with advantage, have been given a wider range; however, taking the title literally, the author has discussed it from his standpoint in all its material bearings. From the time of building up the colonies, in preparation for the honey-harvest, to the removal of the honey from the hives, the ground is well covered.

If I have not misunderstood the author heretofore, he has made a marked advance toward the doctrine of spring protection of bees, and urges strong arguments in favor of thorough early packing to insure rapid breeding, and a strong force of bees at the opening of the honey-harvest. While some stand off and jeer at one who changes his position, and will not themselves move when increased light reveals their feet sinking in mire, I am always hopeful of getting some valuable information from one who shows a ready disposition to put aside previous error.

I accept Mr. Hutchinson's doctrine; but as to method, I prefer, as being more convenient, good division-boards and chaff or sawdust in the super. The author, as one of his chief points, discusses the methods of hiving swarms in hives without foundation in the brood-chamber, so as to secure worker brood-combs, and an increased amount of comb honey, and sets forth all the requirements so fully and clearly that no one who reads the work need fail of success in pursuing the same plan. With Mr. Hutchinson the only thing that stands in the way of complete success in securing the entire exclusion of drone comb from the brood-chamber are the old queens, and he objects to destroying them on account of the additional labor thereby imposed. I think, however, that a queen that is even two years old, and has passed the time in the current year when bees from her eggs can be profitably reared for honey-gathering, can be profitably replaced by a young queen; and I believe it may be done at that season of the year at very little cost.

In addition to the methods advised in the book, for clearing the bees from the cases in removing

honey from the hive, I would strongly advocate a good quill with which to brush off quickly the bees which cling to the bottom of the case as it is raised from the hive; and I would not overlook the utility of the tent with a hole in the top, in ridding the honey of the few bees remaining. The idea of using a tent for this purpose originated, I believe, with myself, and I consider it a valuable aid to one who has a good honey-house, and almost indispensable to one who has not.

For comb-guides in brood-frames, Mr. Hutchinson has found no good substitute for starters of foundation. I have tried a small three-cornered strip of pine tacked to the center of the lower side of the top-bar, the lower corner of the strip having been previously dipped in melted wax. From the limited experience I have had with it I am disposed to think it a good substitute.

The value of a book does not depend on the number of words it contains, high authority in bee-lore to the contrary notwithstanding; and it does not necessarily cost less labor to write a few words than to write many; but there is no froth nor surplusage in Mr. Hutchinson's work, and, judged by the true standard of substantial worth, it must be considered a great success, and no one of the class to whom it is dedicated can afford to ignore it.

Lapeer, Mich., Apr. 17, 1887.

R. L. TAYLOR.

SOME USES FOR HONEY.

HOW TO PRESERVE FRUIT WITH IT, ETC.

FOR jam, honey can be used instead of sugar with several kinds of fruit. For this purpose, clover honey is preferable to honeys of stronger flavor. With cherries, raspberries, and blackberries, honey gives as good satisfaction as sugar, as far as the flavor and the keeping qualities of the jams are concerned; peach-jam for which honey is used, ferments too readily; but honey is superior to sugar to make grape-jam. Grapes, canned alone or put up with sugar, will have crystals of tartaric acid forming among them, after being put away for a few months. But when grapes have been boiled down with honey the crystals do not form until a year or more after the jam is made, if they appear at all; and, further, for flavor and consistency, honey-jam is superior to sugar-sweetened jam.

SEEDLESS GRAPE-JAM.

Push the pulps out of the grape skins, and keep them in separate vessels; weigh them, and allow $\frac{3}{4}$ of a pound of honey to each pound of fruit. Put the pulps in a granite or a brass kettle, and allow them to boil until the seeds are well loosened, then strain through a sieve. Return the thick juice, thus obtained, to the kettle with the skins and honey, and allow the whole to boil from three to five hours. The riper the grapes are, the better the jam is.

In our little town, honey is considered a supreme remedy for colds and coughs. I find that there are as many ways of using it as there families who make use of it, though the favorite way among my neighbors is to apply it externally to the chest and throat, mixed with that old-fashioned panacea, goose-grease (whether cures effected by this remedy are "faith cures" or not, I can not say). Some use honey made into candy; others mix it with an equal proportion of butter, and swallow the mix-

ture before retiring; others, again, and I am one of the number, take it at night in a cupful of very hot water, or, better, elderberry-tea. I have read lately, that honey, well heated, and swallowed by spoonfuls at short intervals, is a sure cure for catarrh.

A great deal more might be said about the therapeutic value of honey, but I shall only add here, that it is unequaled by any other food to cure costiveness, especially in young children.

Only a few people understand to how many uses honey can be put on the table. I would advise the reader to try it as a sauce for baked apples, and for fresh blackberries instead of the regulation sugar and cream. It is not only more palatable, but, for those who live in the city, it is cheaper and more healthful.

I have received lately, from Mr. Chas. Dadant, the following recipe, which he translated from an Italian paper:

HONEY-CAKE.

Work together equal weights of honey and flour; add spice to taste, and the right proportion of baking-powder. Keep this dough in the cellar, and bake it as you need it, in a very slow oven. The cakes will be all the better if the dough has stood for a long time. Honey-cakes are very healthful and digestible, and their use is to be recommended to persons suffering from colds or sore throat.

Mr. Root, would it not be a good idea to induce all the housekeepers who read GLEANINGS, to send you items about some of the ways in which honey is used in their family?

MRS. E. J. BAXTER.

Nauvoo, Ill.

WAX FROM OLD COMBS.

A HANDY DEVICE AND HOW TO MAKE IT.

A CORRESPONDENT writes: "Do you know of any way to get nearly all of the wax out of old black comb? It is easy enough to get the wax from new combs or cappings, but quite another matter when old combs are to be rendered. If you know of a plan which will give the larger portion of wax from such combs, please give it to us through GLEANINGS." It would seem from the many articles given upon this subject, that no more should be necessary; but as in some essentials my plan of rendering wax is different from any I have seen described, I will give it. For bits of comb, cappings, etc., the Swiss wax-extractor works well; but for a lot of old comb, I know of no way equal to a caldron kettle, outdoors, filled two-thirds full of water, with a fire under it. With this, used as I shall soon describe, I think I can get fully 98 per cent of all the wax out of such comb, and rather more for each square foot of such old comb than I can from new. Instead of hanging the kettle over the fire, as is usually done, take a measure of your kettle on the outside, a little way up from the bottom, and go to your blacksmith and tell him you wish a piece of old heavy wagon-tire, welded so that the inside shall represent your measure. To this you want three or four (the latter preferable) square or round bars welded, at equal distances apart, for four legs. These should be of suitable size to give strength enough to support the weight of the kettle and contents, and long enough to raise the kettle from four to six inches from the ground at the lowest point.

After getting the kettle-holder home, place four flat stones just under the surface of the ground, at proper places, so that each leg will rest on one, having it at such a point as will be handy for all of the work to be done with such a kettle, such as heating water at butchering time, boiling potatoes for the hogs, etc.; for the smallest part of the work our iron friend will probably do is getting out the wax. After once having a kettle fixed in this way you will never want one hung on two stakes or a pole. Besides the kettle you will want a sack made of burlap or some other stout open cloth, which you are to fill with the old comb, stamping it in so as to get all in as compact a condition as possible. Next take a piece of four-inch soft-wood plank, or two pieces of two-inch plank, spiked together, and round one side of it, so it will fit the bottom of the kettle. To the flat side of this, fasten (by cleats or otherwise) a standard of a suitable length, which should be flattened at the top and have several holes bored in it. Then get a 3 x 4 scantling, or a suitable pole from the woods, and mortise through it near one end for the top of the standard, boring a hole through it in an opposite direction for a pin or bolt to pass through it and the standard. Besides this you will want a log-chain when we are ready. Fill the kettle two-thirds full of water and bring it to a boil, in doing which use only light fuel, so as not to have a hot fire except for the time being; because, if otherwise, it would be too warm for working around it, and might boil over. Now put in your sack of old comb, and with an old hoe press and squeeze the sack against the sides and bottom of the kettle, rolling it over each time as you press. The wax will rise with each pressing of the sack; and if the comb is not all in, you can soon raise the mouth of the sack out of the water. After it has cooled a little, untie, fill up again, till all is in. When all is in, and the sack has been worked over several times with the hoe, take the log-chain and fasten each end to the ears of the kettle, while the middle of the chain is to be fastened to the short end of the scantling. Now put the rounded-plank end of the standard on the sack and sink it to the bottom of the kettle, when the top end is to be inserted in the mortise in the scantling, and the pin, or bolt, put through the desired hole. Now go to the long end of the lever or scantling and see how you can make the wax rise by bearing down. When bearing down, sway the lever back and forth, and from side to side, so as to grind, as it were, every cocoon fine, and thus liberate the wax. When satisfied that the wax is all out, hang a weight on the lever and leave it. Don't go to dipping off the wax unless you have lots of time, and consider it *fun* so to do, for I assure you that the next morning you will find it all caked nicely on top of the water, when you can break it up and get it ready for a second melting, which all wax should have before going to market, or using for foundation. After taking off the wax, take out the sack, empty out the refuse, and rinse and dry, where it and the rest of the implements used are to be stored away for future use.

The description of this seems quite long; but I believe that in practice it is the shortest known process to get out a large lot of wax from old comb. If you think the iron kettle-holder too expensive, set the kettle on three stones. If stones are used they should be first subjected to heat, else

they may fly to pieces and upset the wax. By the above process I got out wax from old comb which, as early as ten years ago, A. I. Root pronounced in GLEANINGS as the best he had ever seen.

Borodino, N. Y., Apr., 1887. G. M. DOOLITTLE.

No doubt, friend D., your arrangement will answer an excellent purpose. I think, however, our friends will be obliged to have the iron legs to the kettle, or the lever would roll the whole thing over, and then there would be a pretty "kettle of fish," or rather, perhaps, a kettle full of beeswax, on the ground and in the fire, instead of in the kettle. I should be afraid, in any case, that it would hardly be safe to put *very much* pressure on your lever, unless the opposite end were more substantially supported than the attachment of it to the log-chain fastened to the kettle-ears. Reports at our different conventions seem to indicate that the only way of getting absolutely all the wax is to have some sort of press to apply to the wax while it is hot. Your arrangement is probably as practicable as any for the average bee-keeper.

BEES IN FLORIDA.

AN INTERESTING LETTER FROM G. W. WEBSTER.

IT has been two years or more since I made any report of our success with bees here in the land of flowers. Two years ago we extracted from 20 colonies about 1000 lbs., or 50 lbs. from each colony. A year ago we had only about 25 lbs. per colony. The season was a very cold one for Florida, and the bees dwindled to mere nuclei. A few died. It would seem to any one used to Northern winters, that Florida must be a nice place to winter bees; but there are serious troubles in wintering, even here. During the cool weather that we have here in winter there is not steady cold weather to keep bees in the hives. An occasional frosty night, and the absence of any honey-flow, checks brood-rearing, while every warm day the bees come out in search of honey or pollen, and many of them become chilled and never get back. Every experienced bee-keeper will understand how that would work.

A year ago last August I was taking care of 75 very large colonies of bees in chaff hives at Bonair, Iowa. After a few weeks of hot weather, with the mercury keeping pretty close to 100° in the shade, there came on several days of cold weather. There was plenty of buckwheat honey in the fields. The bees would go out, and, coming back loaded with honey, thousands of them fell and could be seen crawling over the ground. I have no doubt that I lost more bees every day for awhile than would make a large colony. Here in Florida we sometimes have such weather two or three days in a week for several weeks at a time. In our locality bees do well if they find enough honey to live on after the first of June. A nucleus on four or five frames will often starve out before the next season for honey commences, which will be in January, February, or March, according to the season. Strong colonies that have 25 or 30 lbs. of honey will generally come through in good condition.

In my opinion, the idea that bees get lazy in warm climates, and will not work, is all nonsense. They will work like beavers whenever there is any

thing for them to get. Leave honey or any kind of sweets around where they can get at it, and they will soon convince any one that they are not lazy. We have to keep the entrances to the hives contracted during a scarcity of honey, to keep them from robbing. We generally have to feed weak colonies in November or December. Our method of feeding is not patented.

For extracting we use long hives with a division-board. When we wish to feed we move the division-board and combs if necessary, so as to get the honey near to where the bees are clustered. We then take a bottle holding two or three pounds of thin honey, tie a piece of very thin cloth over the mouth, and place it in the hive, mouth down, just so that the honey can all run out, the other end of the bottle leaning against the side of the hive. The bees work away at the honey till it is all gone. Once a bottle was so placed that the honey could not all run out. The bees gnawed a hole through the cloth, got into the honey, and a lot of them were drowned. We knew better next time. There is not enough honey around to excite robbing, and it is very little trouble to feed them with our hives. The high, open, pine woods where most of the settlements in this part of Florida are, do not afford much honey at any time of the year. There are some scattering flowers during every month, but not of a kind to yield much honey. Where there are bearing orange-groves, bees gather some surplus honey during the latter part of winter, but I have seen no heavy yield of it.

Locations like ours, where there are plenty of lakes and ponds bordered with ilex, glaber (gall-berry), and palmetto, yield a good quality of light honey—the gall-berry about April, and palmetto in May, varying to the season. We think the gall-berry honey is best; but either is better than orange honey, which is darker, and nearly as strong as buckwheat honey. There are a few locations on the coast where the mangrove yields honey by the ton, but those locations are already pretty well monopolized, and honey is cheap. We have been wholesaling ours at 7 and 8 cents per pound.

To sum up, I will say to bee-keepers wishing to come to Florida, that high pine land is a total failure. Where there is plenty of palmetto and gall-berry, or rich hummock land near, it will be nip and nip to make a few colonies pay. A good mangrove location will be pretty good if one can stand mosquitoes, sandflies, and malaria. Of course, experienced bee-keepers will keep a few bees wherever they may be located, but I could not recommend any one to go to any place that I have heard of, away from the mangrove, with the idea of making bee-keeping a business.

It is the climate of Florida that brings people here. The winters generally have but few frosty nights, and sometimes none; and in the summer I have never seen the time that a thermometer, placed in the shade where there was no hot sand or any thing else to reflect the heat, would indicate more than 93°. People with plenty of money can enjoy themselves in this country, but I do not call it a very good place for a poor man. Yet there are many laboring men who are doing well. Fruit-raising is the principal business, especially raising oranges, in this part of the State. It would be interesting to write of the winter resorts and beautiful villages scattered over the State, of fine residences, owned, of course, by wealthy people; of

steamboating on the St. John's or sailing on the Halifax and Indian Rivers near the coast; of the fresh oysters and fish there; also millions of water-fowl at times; of fine strawberries from January to June, and of the many other fruits raised here; of fresh vegetables all winter, and many other items.

G. W. WEBSTER.

Lake Helen, Florida.

HOW BUSY FARMERS CAN RAISE STRAWBERRIES.

FRIEND TERRY SHOWS THE POSSIBILITIES RESULTING FROM HOME EMPLOYMENT.

FRRIEND ROOT:—About this time of year farmers are all advised by the horticultural and agricultural papers to set out a strawberry-bed. I probably heard 20,000 of them advised in this way at the institutes last winter. I heard them told, sometimes, that it was as easy to raise a bushel of berries as a bushel of potatoes. This talk is all very well for the men who sell the plants; but how do strawberries usually thrive under the management of the ordinary farmer? I think it safe to say, that, nine times out of ten, the berries picked do not much more than pay for the plants. The farmer is so busy, and has so many things to attend to, that the strawberries, like the garden, will not be likely to get the care that they need. It is quite a science to raise large crops of fine berries; one must read and study, and then attend to them at just the right time all through the season. This pays finely when one makes a business of it; but I have long had my doubts whether it would pay the ordinary farmer to fuss with a few, if he could buy fresh ones of a home grower. For some years we have bought about five bushels a year, as I thought I could raise potatoes and wheat, which were right in the line of my business, and for which I had all the tools and experience, and make the exchange for berries and be the gainer. I have tried raising them, or, rather, setting out the plants, with much care, and finally, in the rush of the season, neglecting them so that we hardly got our money back in inferior berries. I am ashamed to say it, but it is the truth; and I know I am not alone in my experience. Hence I do not believe it is much use to urge farmers to set out strawberry-plants in the usual way. But notwithstanding all this I have a fondness for seeing the berries growing, and I have been thinking it over all winter to see if there were not some way I could manage so the berries would be properly cared for. One day my girls were telling me that they wanted to do some work away from home, so as to get some money.

"Why," said I, "I will furnish you what you want; you earn it in taking care of me."

"Yes, I know you will," says one; "but I want to earn it myself, where it won't come out of your pocket."

It struck me this was a laudable ambition, and still I could not think of their going away to teach school, or any thing of that kind. All at once the strawberry-business occurred to me, and I asked them how they would like it to take charge of the whole matter and pocket the money.

Well, the result was I gave them the nicest, richest (mark that—not some poor corner) piece of land on the farm, and have engaged from a reliable

grower, the well-known Matthew Crawford, what plants they will want, leaving the choice of varieties to him. I have bought them books enough to study, so they can learn all that is possible in that way. We men will plow the ground when we do the rest of the lot, and harrow and roll it; and then when we are cultivating potatoes we will run through the berries; but the girls are to take the whole responsibility. I think it will do them good. It will teach them business. It will be healthful work. If berries could be raised in this way, on three or four farms in every town, I think it would be the best way for the farmers and for the individuals who own the patches. I do not hesitate to advise any farmer or other person to go at it in this way.

I asked Hon. H. C. Adams, of Madison, Wis., a noted raiser of berries, how much land my two girls, with their brother to help them, could take care of. He said he could tell better if he could see the girls. If they had lots of vim, an acre might not be too much; but still, he guessed half an acre would be safer. I thought best to cut down nearly a half on that, not on account of lack of vim, but because I have learned that concentrated farming is best, in the berry-patch as well as elsewhere. In a year or two they can spread out a little, if desirable.

It would be better, perhaps, to wait and give the result before advising other parents to go and do likewise; but time is too short. I take it there are hundreds of readers of GLEANINGS who could set up their children in a little business in just this way. It will cost only \$5.00 or \$6.00 for plants.

About the market: Make one among the people living right around you. There are ten bushels of strawberries sold in Hudson, where I live, now, where there was a quart when I first came on the farm, and the end is not yet by any means. Plenty of people would buy nice fresh berries, at a living price, if they were put right before them, who hardly know the taste of the fruit now.

Now, I want to stir up the children as well as the old folks a little by telling what has been done on a single quarter of an acre. I have seen the ground, and spent four days with the man who did it—the venerable J. M. Smith, of Green Bay, Wis. It was not convenient to measure all the land and keep track of the crop, so our friend marked off one-fourth of an acre and picked from it 3571 qts.—the largest crop, it is said, on record. Just think if you do not know of hundred-acre farms that do not do much better. At 10 cts. a quart this would be \$357. This is enormous, but not greatly above Mr. Smith's average. From $3\frac{1}{4}$ acres last year, although terribly dry, he sold \$215.24 worth of berries, besides taking plants to the value of \$300 from the same land in the spring. But this was not enough. After the berries were picked he plowed the patch and put in cabbage and celery—\$700 more! Just \$3215.24 from $3\frac{1}{4}$ acres of land! I took the figures right from his books, where each day's sales were put down. There isn't a question about their exact truth.

Now, friends, do not let the children go away from home to work just yet, so as to be earning something, when you have plenty of land that is not bringing you five dollars an acre; certainly not, if, from the fourth part of a single one, there is a chance for them to earn one hundred dollars or more. These figures I have given are from the

"upper story" — from the most skilled grower, perhaps, that we have; but in books and papers he tells every one how to do it. There are no secrets. Mr. Adams told me, that in a large way he had raised, on an average, not less than 160 bushels per acre, which brought \$400, and this for a long term of years. Just think of it! he sold last summer, to one restaurant in Madison, strawberries and cream to the amount of \$1000!

Now, if I stir up any father to give the children a chance, I shall be glad. Early in May will answer to set out the plants; but the sooner the better. The men you buy of will tell you how. Deal only with honest home growers, and take their advice as to varieties, etc.

T. B. TERRY.

Hudson, O., April, 1887.

There, friend Terry, you have written just exactly the article I wanted you to write. I have considered a good deal the thought you have made in many of your writings, that it is not only cheaper, but that a man enjoys himself better to have his specialty. I have had enough experience to understand the full truth of what you say about preparing yourself with proper tools, and studying up your subject thoroughly, and then doing the best that can be done with one specialty. In my life I have taken up a great many different kinds of business, and I have eventually made a success with a good many of these ventures, but it has always been a slow process. When I felt that I wanted to publish a bee-journal, I did not feel satisfied until I owned the type and the printing-press, so that I could have every thing just as I wanted it. The hands who were then working for me were not printers; but rather than leave my employ they consented to go to work and learn how, and I took the lead for a while, by learning to set type myself. In time we got out a pretty fair bee-journal, as some of the friends may remember; but *I tell you* it took days and nights of *hard, earnest work*, and while I was at the printing other things received but little attention.

Now, I know by experience that it is a task for a farmer to stop to plow even a little patch of ground for a garden. While we have been hauling manure this spring, several have wanted *just one load*, and then a few more particular friends wanted us to take our big team and stop just long enough to plow a garden; but I do not believe it would have paid us, even if we had been offered three times the usual price for such work, for the digression would have interfered with our regular plans. It would have thrown some others out of work; and may be the loss of just two such hours would have prevented us from getting in a crop at just the right time, and I can readily see that a progressive, successful farmer could by no means stop his work to fuss with a strawberry-patch. Before he could make any of the large results you mention, he must give the business a part of his *brains* as well as of his acres of ground. If he *loves* growing strawberries, however, and it is a pleasure and recreation to him, this would make another thing of it altogether. But I should expect, even then, if he succeeded *well* with his fourth-acre of strawberries, he would lose in his regular farmwork as *much, or more*, for it would take some of his brains

and energy from some of these things. The moral to the above would be, be careful about scattering your energies; concentrate them upon one kind of work, and make that work a success. Some one may suggest that we *hire* somebody to take the necessary care, pains, and responsibility to make the strawberries succeed, as well as regular farm crops. All very well and good, providing he *can* hire somebody who is competent to the task. My experience has been, that one who can make these big results on a small piece of ground prefers to work for himself. Suppose, however, it is *your own boys and girls* who feel an enthusiasm to enter the great business world, and try their skill independently of father and mother. This makes another thing of it entirely. You can afford to stop your team and lose a crop; you can afford to lose almost any thing rather than to lose an opportunity of teaching your children how to help themselves. It is, in my opinion, one of the grandest schools, for any young man or woman to go into some sort of business in just this way; and the results that have been attained from these industries, small fruits, bees, poultry, etc., have proved beyond question that it may be done. Let the *young folks* supply the needed brainwork; the exercise will develop their talents for business, and these outdoor industries strengthen the body as well as mind. Some writer has said, that, if you get a man or woman full of enthusiasm in these rural industries, they are almost proof against disease; and I believe that, a great many times, this thing alone will make sick people well. The girls may get sunburned, and perhaps tanned somewhat, by being outdoors so much; but, judging from my own experience, I think they will get repaid a hundred times by the happiness and enjoyment such work affords, especially if they succeed in making *some money*.

I hardly need suggest to *you*, friend Terry, how much depends on having some ground that is easy to work, and up to the highest notch of fertility. One of the bee-friends who lives in Barnesville, Ohio, paid us a visit recently, and I questioned him a good deal as to how they succeeded in raising the great big strawberries that bring such fancy prices. I have just received fifty of the *Jessie* strawberry-plants from your neighbor Matthew Crawford; and when I want to get happy I go out and look at these plants, and loosen the earth around them with my fingers. A bright, thrifty, rapid-growing strawberry-plant is one of the handsomest products of the floral kingdom, to me. And then the wonderful facility with which the runners may be made to produce new plants makes the business intensely interesting and fascinating. Perhaps some of the friends thought I had got over my strawberry craze, but I tell you I haven't. It is the plants and vegetables that we love that make the wonderful results; and where your children have a natural taste for handling and studying the habits of any plant or animal, they are the ones to make it do its best. May God bless your girls in their work, and may he bless the boys and girls, too, in all these homes scattered over our land!

HEADS OF GRAIN FROM DIFFERENT FIELDS.

THE SIMPLICITY SIMPLIFIED.

I HAVE 13 colonies of Italians in two story Simplicity hives, made by G. B. Lewis. I also gave E. A. Armstrong an order for 50 of his new reversible cases, made the size of my hive, holding 28 sections each. Now, I have changed the upper and lower stories into brood-chambers, making 26 hives out of 13 by dressing off the bevel edge and tacking on strips to bring them up again just $\frac{1}{2}$ bee-space above the brood frames, and then all is ready for the super. My covers are made like Dr. Miller's, except mine have a $\frac{1}{2}$ bee-space strip around the inside edge, corresponding with $\frac{1}{2}$ space on the super. I use Simplicity bottom-boards, making them long enough for alighting-boards, and all in one piece. I also have as many slatted honey-boards as hives. One side up they are break-joint; the other side is one continuous passage.

My hives and supers are painted three coats, pure white; the edges of honey-boards are jet black; all above the black line is mine, and all below belongs to the bees. I would say, also, that, while my supers are reversible, I am not compelled to reverse, nor do I expect to practice it, having already tried it sufficiently to convince me that it is nearly always impracticable. The cases would be better if made plain on three sides, and open only on one, costing less and accomplishing the same. The good things about the case are the T tins, the wood separators, wedges, and the simplicity of manipulation. I call my hives now the Simplicity simplified.

W. G. SECOR.

Greenfield, Ill., Apr. 6, 1887.

AN A B C SCHOLAR TELLS HOW TO EXTEMPORIZE A BUZZ-SAW OUT OF AN OLD FANNING-MILL.

I saw in GLEANINGS that Walter S. Pouder tells something about rigging up a buzz-saw. I will tell you how I made a hand-power saw. Take an old fanning-mill, having two good cog-wheels. Remove the hopper and put on a saw-table. Under it place a \$2.50 mandrel. On the wooden mandrel of the mill put a pulley. Belt the latter to the saw-mandrel pulley. Your saw-table is now complete. Take hold of the crank and turn as if you were cleaning wheat, and your buzz-saw will just hum. Your pulley ought to be 15 inches in diameter, with a five or six inch saw. It will run very easily, and you can rip up any thing where the saw will reach through. I have two of these saw-tables in use. One has a \$2.50 mandrel and a 5-inch saw, and the other one has a \$4.00 mandrel and 7-inch saw. With one hand I turn the mill and with the other hand I put the boards through. I prefer the table where the 5-inch saw is on. It runs much easier than the 7-inch saw, because the table where the 7-inch saw is run on must have a larger pulley, and so it will run harder. My 7-inch saw makes over 2000 revolutions a minute at ordinary turning, and I can rip up an inch board in a great hurry. I make all my bee-hives with these saws, and lots of other work besides. I think saws run in this way work pretty well for beginners.

Douglas, O., Mar. 28, 1887.

H. D. FRIEND.

WHY WERE THE BEES TORN TO PIECES? HUTCHINSON'S PLAN OF SWARMING.

Our bees have just had a fly, and three of them were engaged carrying out parts of bees. They were torn all to pieces, while the rest were bringing out bees not torn to pieces. The entrances are $\frac{3}{4}$ of an inch deep. We opened one of the hives, but could see nothing wrong. Can you tell me the cause of the bees being torn to pieces? We received 60 lbs. of comb honey per hive, spring count, almost all from white clover. There was no basswood bloom this past season, while in 1885 it was our only source. Bees are mostly kept in box hives here. The Hutchinson plan of hiving swarms works very well with us. In one instance they came out and clustered. On opening the hive the newly made combs were filled with eggs and pollen. We put in a frame with honey, and rehived them, and they were all right. I suppose, on account of no honey in the brood-nest, and the queen not getting any thing to eat, the bees were starved out.

Moundsville, W. Va., Dec. 11, 1886. C. C. SCHWOB.

Friend S., I can not tell what tore the bees to pieces, unless it was mice; but if your entrances were no wider than $\frac{3}{4}$ of an inch, I do not see how the mice could get in. I have seen a sort of worm among the dead bees, suck out the juices, and leave them a good deal in the shape you mention. Was not this the way it came about? I can not quite imagine how you or friend Hutchinson, or anybody else, could so arrange your hives that the honey went into the sections so completely as to starve the queen and bees. I never saw a comb of brood yet that did not have more or less honey and propolis scattered about in it somewhere.

WHAT COMPENSATION SHALL WE RECEIVE FOR TAKING CARE OF ANOTHER'S BEES?

I should like to inquire in regard to the customary wages of those having the care of bees. I expect to take charge of an apiary of 132 colonies in chaff hives. I shall have to put together hives, frames, sections, make fdn., extract honey—in fact, do every thing connected with the business. What I wish to know is, what would be reasonable wages for six months, commencing the first of April? Or if I should do the work for a share of the season's income in honey, what should be my share, the owner furnishing every thing? In either case I am to board myself.

In hiving swarms last season it happened two or three times that the queen was lost. I noticed that those swarms built out their fdn. and filled up with honey as fast or faster than those that had queens and reared brood. Of course, a swarm left in this condition would soon begin to grow weak. But could not this habit of bees be taken advantage of where honey is desired instead of increase? I have a plan in my mind which I will state. To make the matter plain we will suppose we have but two colonies, which we will call Nos. 1 and 2. The plan is to remove the queen from No. 1, and, as fast as they fill their combs with honey, take it from them with the extractor. To keep No. 1 up to full strength, give it capped brood from No. 2, using the extractor also on No. 2, in this way getting a large yield of honey without increase of colonies. If, on the other hand, comb honey be more desirable, use sections largely in the brood-chamber of No. 1. These thoughts may not be new to you, but in

my reading of bee-literature (which is quite limited) I have not come across any thing like it, and I should like to have your opinion. H. L. DOTY.

Salem Center, Ind., Jan. 28, 1887.

Friend D., I have sometimes thought that it was harder to decide just what a man who takes charge of bees is worth, than in almost any other occupation. For instance, a man who is sharp, keen, and skillful, might, with our 200 colonies, raise 1000 queens in a year, while another, equally honest, and working equally hard, might not raise more than one-fourth that amount. If the latter man is worth a dollar a day, the other would be worth four dollars, and I presume almost as great a difference would be found in the production of honey. It has been said, that no one knows the possibilities of a single colony of bees in a single season, and I should say that no one knows the possibilities of a single *man* in a single season. We do know to our sorrow, however, that there is an abundance of men who do not accomplish enough to pay for the wages they receive, and these are they who are going about from place to place, hunting for a job. Within the last hour I have employed a man to assist in our apiary, and I told him we would pay him whatever we found him to be worth. I have just unloaded a load of bees which we are to buy of him; and he drove off, saying, "Look the bees over when you get ready; and when I come around, allow me what you think I ought to have for them." It seems to me this is a very fair way to decide any of these difficult matters, especially where we have not seen the man work, and do not know what he can do. These bees we have not overhauled and examined yet, therefore we can not tell what they are worth to us. In the latter case, of course we want to deal with men whom we feel sure are disposed to be fair. Working on shares is always a complicated business; and about all that we can say is, arrange it in any way that you can agree upon.

THE "BOY BEE-KEEPER" REPORTS AGAIN.

It has been many days since the "boy bee-keeper" last appeared in your columns, and you and many of your readers may now scarcely recall him, so far have we drifted from our Georgia home at Hawkinsville, where our venerable sire still holds the fort with the gentle golden-banded Italians. We observe with especial interest the bees and flowers of every section we visit; and the result in this State has not been all we had cause to expect. We have wandered searchingly through woods and groves where the zephyrs came to us laden with the perfume of many flowers, and found a few small black and one yellow-banded bee to reward our pains. This only shows how that most delicious and wholesome of sweets is permitted to "waste its sweetness on the desert air," for no section of the country has given more abundant yield than some portions of Florida, where the industry has been properly introduced and scientifically pursued; but we find large areas of almost totally unoccupied territory. We shall make some practical tests in regard to this immediate field, and will probably, with your permission, give something of the result to your readers. CHAS. R. MITCHELL.

Ocala, Fla., Apr. 16, 1887.

EASING DOWN A SWARM.

I see some details of how some parties manage to get down swarms from high trees. I go up the tree and take a line stout enough to bear the swarm, throw it over the next limb above the swarm, then bring it down and tie to the limb holding the swarm. I then saw off the limb with the bees and let them down over the above-mentioned limb. If no limb is convenient, I let it down hand over hand. By having the line to bear on I can ease the limb down without any jar when sawing off. WM. HALL.

Romance, Wis.

Very good, friend H. Your plan for taking down a swarm will work all right if you have a limb above the one upon which the swarm was clustered, and if there are no limbs below to interfere in easing the swarm down. We have never yet succeeded in making a swarm cluster just where we desired it to. A perfect method of taking swarms down should be one that would be applicable to all conditions, and to any height.

MORE ABOUT THE COLONIAL EXHIBITION—A CORRECTION.

On page 252 Ernest seems to think the honey-exhibitions at the C. & I. E., made by the British Bee-Keepers' Association, and that made by the Ontario B. K. A. were one and the same. To think so would be quite a mistake. Our friends in Britain held their exhibition (if my memory serves me) from July 30 to August 4. Then it was removed. Ours was placed in position about the middle of September, remained open until the close of the exhibition, on the 10th of November, and was held in quite a different building—one erected expressly for our exhibits. It was occupied by our honey only. Yes, the colonial was lighted by electricity by night, and there were three arc lamps in our honey-building, and, as you may well imagine, the effect was very pretty. I am really sorry, Ernest, that you were not there to see it. Thanks for your kind remarks about our honey-shows. You are right about exhibitions helping sales. A lot of granulated honey in glass educates the people remarkably. The photographs shown by Mr. Abbott were of British honey. S. T. PETTIT.

Belmont, Ont., Can., April 6, 1887.

Thanks, friend P., for the correction. We did not know before that the exhibitions were held in two different buildings, and at two different times; in fact, in looking the matter up we did not notice but that they were one and the same exhibition, all held in the same building. We should have very much enjoyed taking a view of the honey-displays.

FURTHER EXPLANATION IN REGARD TO THE OAK-GROVE APIARY.

You don't know how much good it did me when I got GLEANINGS of March 1st. I opened it and found a picture of my apiary. I will now explain it some. The girl with the light dress is my sister. The little boy, as you call him (he is almost as big as I am) is my brother, and the other girl is my cousin from Nebraska. You ask why I put the hives on stilts. They are only 6 or 10 inches high. They look higher than they are. I put them that way because the frogs eat so many bees at night. The young bees never get chilled here when they fly out. The

peach-trees are quite full of peaches. Some of them are as large as a hulled walnut, and they will be ripe in May. Yes, there are orange-trees all around the apiary. Ours are not old enough to bear yet. There is a garden at the other side of the picket-fence, but the house comes first. I will explain that I have changed the name of my apiary to Oak-Grove Apiary, and my address to Barberville, instead of Volusia. Bees are doing pretty well, and we are having some swarms. When you come to Florida, don't forget to make us a visit.

Barberville, Fla., Mar. 21, 1887. O. E. HEACOCK.

DRONE-EATING CHICKENS ALSO WORKER-EATERS.

I think Mr. Cather will find, if he allows his chickens to catch drones, they will soon become as good worker-eaters, and, despising the sting, they will learn to handle them in as easy a manner as they do the poor helpless drone. I killed a chicken last fall that became an expert at the business. On opening the crop I did not find over three drones, but about ten times as many workers. My experience teaches me to keep the chickens out of the bee-yard. They dirty and scratch up the ground we have taken pains to lay out and level off; and on a fine winter morning (when it is too cold for the bees to come out) you may find them on the sunny side of a hive, jabbering off their chicken-talk, which must be very annoying to the inmates who are trying to pass away the cold winter in quiet. GRANT SCOFIELD.

Ridgway, N. Y., April 8, 1887.

THE FIRST DRONE.

Bees have been gathering pollen at times for two or three weeks, although we have had several quite severe freezes during the time. Yesterday they were very active, almost as thick around the hives as in summer. I thought at first I had a case of robbing on my hands, but some were busy carrying in pollen, and probably the others were young bees at play. I noticed one drone, the first I ever saw so early in the season. Am I to expect a swarm from that hive soon? It is a Langstroth chaff hive, containing a last year's first swarm. Or was I mistaken, and, instead of a drone, was it one of P. Benson's bees that he had fed up with his nursing bottle? S. C. GORDON.

Georgetown, O., Apr. 9, 1887.

The presence of drones may indicate that the bees are thinking of swarming; but as they often start a month or two before they swarm, it does not indicate any thing very positive.

CIDER, AND ITS EFFECT ON BEES IN WINTERING.

Mr. Dunn's remarks in last GLEANINGS, on the effects of cider on bees, induce me to relate my experience with it. In the fall of 1884 I had 27 colonies in winter quarters, packed on summer stands. We have a cider-mill within 30 rods of my apiary. The fall was warm, and they took large quantities of cider. About the 20th of November I found large quantities of brood in all the hives. That season, you will remember, was very productive of honey-dew, and the winter was very cold. When the February thaw came I had lost eight colonies, then six weeks cold, and I lost 16 more—24 out of 27. From the combs I extracted over 400 lbs of honey-dew.

In 1885 I put 28 colonies into winter quarters. They took a great deal of cider, and in the last part of November I found the hives well filled with brood. I lost one colony, starved, because, though

they had plenty of honey, it was at the other side of the hive.

In 1886 basswood blighted, and then drought came. A good deal of honey-dew was carried in, and but little honey from autumn flowers. The fall was warm, and the bees worked at the cider, taking a great deal. Brood-rearing had stopped in September, but began again; and on the 19th of November there was a good deal of brood. All my friends predicted heavy loss. The bees being short of stores, I fed about 300 lbs. of granulated sugar, in hard candy, laid on the frames. The work in the cider-mill interfered with feeding them early enough to make syrup. I packed 25 colonies with pine planer shavings; 18, including 3 so weak that I hardly expected to winter, I put into a clamp.

Jan. 21 there came a thaw, and I opened the clamp so as to give the bees flight. They spotted the snow no more than others wintered on natural stores without cider. I took them out on the 7th of April, having closed up the clamp again on the evening of January 21. All were in good condition but one; they having some packing one side, dug it out and so stopped up the entrance, and smothered. All on summer stands wintered well. I extracted all unsealed honey from about half the hives, in the fall; part of these were in the clamp, part out. I did not see that it made any difference.

Nelson, O., April, 1887.

S. J. BALDWIN.

HONEY-POISONING; HONEY SUPPOSED TO HAVE BEEN GATHERED FROM POISON HUCKLEBERRY.

I was raised in the central portion of Texas, and lived there 25 years, when I moved to this country two years ago, on account of poor health. I had liver disease, which baffled the skill of several physicians in Texas. I have improved so much since I came here that I feel as sound as ever; but when I undertake heavy work I soon become exhausted. I believe if I were to remain here it would finally cure me.

The country is very rough here—too much so to make any speed at farming. It is a heavily timbered country, consisting chiefly of oak and pine—some basswood on the river, three miles east, but little land under cultivation. Water is abundant. Nearly all the little branches between the mountains run eight months in the year. There are a good many wild bees in the woods, but yet very few people here have tried raising bees at home. They say they would rather hunt for the "wild" honey in the woods than to be bothered with bees at home. Several persons have been poisoned with honey in this part in the last two years. It is unknown what the cause is of the honey being poisonous. Some say it is strychnine which the bees got from bait put out for wolves. Some say it is poison huckleberry, but both seem improbable when we consider that there is not a tenth as much strychnine put on now as there was six or eight years ago, and the huckleberry is no more plentiful now than several years ago. As before stated, the first case of poison was two years ago. In a few hours after eating the honey, the persons poisoned begin to feel a tingling in the fingers, which finally extends over the whole body. In some cases it has caused partial paralysis, lasting several weeks. One case occurred ten or twelve miles from here, where a whole family of four persons were poisoned, and died within 24 hours. They lived in the low bottom country. At all of the places I have visited, where poisoned hon-

ey was taken, I have found plenty of poison huckleberry near by. If you can explain the cause of this poison, and give a preventive, it would be a blessing to many persons in this and perhaps other sections.

W. R. DAVIS.

Ultimathule, Ark., Feb. 15, 1887.

I have never heard of a poison huckleberry, friend D., but there has been considerable said about poison honey in years past. In a talk with Prof. Cook, a few days ago, while looking at specimens of honey in the museum of the Agricultural College, he expressed a belief that there is more or less mistake in regard to the whole matter. He has a sample bottle of poison honey in the museum; and, if I am correct, he has eaten it without any unpleasant results at all; and I am inclined to think that any thing that would kill a human being would kill the bees themselves. Sometimes one or more people in a family die after having eaten articles of food put up in tin cans; but we are assured from good authority that the cause of death lies somewhere else than in the canned goods; and I am rather inclined to believe that these deaths may have resulted from some other cause than from the honey that was eaten. We should, however, be glad of facts on the subject.

A NOVEL SWARMING-BOX.

I send you a sample of a swarming-box that I have used the last season. It works like a charm. There is no shaking of swarms to get them out of the box; all you have to do is to get your swarm to cluster in the box, the same as with any other box, then take the box down with the swarm in, and stand with your left hand to the box, with the pole at your right hand; walk up to the hive you wish to put the swarm in, lay it down with the open end to the entrance, or, rather, to the right, as you stand, then loose the hook and spread the box out and your swarm is ready to run in without any shaking or trouble. This is my plan and invention, and it is free to all who wish to use it. You can give the plan to your readers if you wish. The box is about 7 x 7 x 18 inches.

G. H. CLEMMER.

Arcanum, O., Mar. 29, 1887.

I will explain to our readers, that the box is much like our own, described in our price list and A B C book, only that it is hinged together with leather hinges, so that by unhooking one side it can be laid out flat in front of the hive. As bees sometimes act contrary, when shaken from a box, and take wing and go off, this might be an improvement; for after it is spread out on the ground in front of the hive, it has lost all appearance of a hive or cavity wherein they could cluster; and without any excitement or disturbance they proceed to march right into the hive proper, as offering the best accommodations after the hiving-box has been, so far as they can see, demolished.

WHY DID THE HONEY BECOME SOURED IN SO SHORT A TIME?

For the last two years our honey has not kept well. In the fall of 1885 we had but little honey. This was dark, with a disagreeable taste, and soon acquired an acid taste in addition. The honey-crop was large in the fall of 1886, and such delicious honey I never before tasted, so thick and clear. An old

and experienced bee-keeper took up the honey for me, and said in all his experience he had never before seen such honey; but inside of three weeks it had acquired the same disagreeable flavor, with the same acidity. Yesterday I met the gentleman who had taken up the honey for me, and he asked me what I had done with all "that delicious honey." I told him that it was not fit for use; and when I had explained he said he had never heard of such a thing in his life. He gave me your address, and asked me to write to you about it. My father-always kept bees, as did my husband's father, and I never heard of such a thing before. Our bees are Italians. We sow buckwheat for them after the fruit-blossoms and forest-tree blossoms are gone. We sow some buckwheat in June, and again later, so that the frost takes it while still in bloom. There are different wild flowers—heart's-ease and golden-rod being more plentiful than other varieties. If you can tell us what the trouble is, I shall be grateful.

LETITIA W. TRUESDELL.

Concordia, Cloud Co., Kan., Feb. 24, 1887.

I am sorry to say, my friend, that I have never known a case just like yours. I have seen honey, however, that seemed very thick and nice after it was thrown out of the extractor, and placed in a deep can, settle so the thickest and nicest honey was at the bottom, while that on top would become so thin as to sour. Is it possible that this is the trouble with yours? If so, go down to the bottom of your receptacle, and you will find it all right.

HONEY FROM ALSIKE.

Your estimate of the amount of honey 100 colonies would gather from 10 acres of alsike is certainly low enough. Now, it would be a difficult matter to get at it with any degree of exactness; but this I do know, that for the last two or three years our average of extracted honey from clover (there is very little of the ordinary white here) has been about 150 lbs. We have not 100 colonies, and have some 30 or 40 acres of alsike within 1½ miles of our apiary. In 1882 we ran 9 colonies for comb honey, and there was only about 10 acres of alsike near. It was a very poor season for honey, and nothing secreted honey during the clover season but alsike. We got about 250 lbs. from the 9.

ROBT. H. SHIPMAN.

Cannington, Ont., Can., Apr. 12, 1887.

TIMELY ARTICLES; WIDE FRAMES.

What a benefit can be derived from timely articles! For instance, Dr. C. C. Miller's article, March 15, p. 206—"Time of Taking Bees Out of the Cellar." My neighbors have taken their bees out since early in March, and we had considerable stormy weather during the last week in March. My bees are still in the cave, for which I am glad. Well, friend Root, I see that those who use supers have their troubles. I have tried supers, half stories, and wide frames in full stories; and if the golden rule is observed, to keep the colonies strong, I think the latter is as good as any; and as far as propolis is concerned, if there were some way of preventing the frame from sagging, so the sections would not drop from the top bar, the propolis would not be so bad.

Cleveland, Ia., Apr. 4, 1887.

E. B. MORGAN.

The trouble you speak of, friend M., was pointed out by Dr. Miller, and we had already made arrangements to make the wide frames tighter fitting for sections.

THE MESQUITE HONEY FROM TEXAS.

I send you by this mail a sample of mesquite honey, also some mesquite-blossoms. I extracted from three hives, April 14, 72 lbs. of honey, equal, every ounce of it, to the sample sent. Our honey-flow has come earlier than common, owing to the long-continued dry weather; and if the drought continues much longer I shall have honey enough, but no bread to eat with it. Try the sample, and tell me what you think of it. M. BROOKS.

Gonzales, Texas, April 18, 1887.

Friend B., the honey you send is of a nice amber color, though not very light, and the flavor is very good—much like some of our best fruit-blossom honey. The blossoms are very pretty and fragrant, even after so long a trip through the mails. If the mesquite yields honey usually in the quantities you mention, it deserves to have a place among our valuable honey-plants.

A HOME-MADE SAW-TABLE.

Inclosed you will find a picture of my sawing-machine, drawn by my boy, age 14. On this I have

made all of my own hives, crates, sections, and other supplies. Last year I made and sold over \$100.00 worth of apianian supplies. This machine I made myself. I bought the saws and mandrel of A. I. Root.

I think we can't praise you too much for the good you are doing through Our Homes and the Tobacco Column. To GLEANINGS and the A B C book I owe most of my success with bees.

New Vernon, Pa.

D. W. BURNETT.

FAVORABLE TO MRS. COTTON, AGAIN.

I was much pleased to read your article in GLEANINGS about Mrs. Cotton. I think she has been somewhat unjustly abused. I sent to her in the spring of 1885 for a swarm of Italians, and increased to six the same year, with 65 lbs. surplus, and last season to 20 and 350 lbs. surplus. I should have done better but for the drought. I think, with you, that her prices are high, but I think her hive is very good, especially for wintering—no small item, by the by. The only objection I have to it is, that it is not adapted to 1-lb. sections, though for my use I should prefer her glass boxes, but they are not so good for the general market.

Fulton, Mo., Jan. 11, 1887.

H. S. HUGGETT.

Friend H., I am very glad to get such a frank, honest testimony as the one you give. When anybody indorses Mrs. Cotton, to the extent of saying that she is exactly right in her plans and her prices, I begin to feel a little afraid of him. It is natural for humanity to take sides on almost all questions. A part will go to one extreme and a part to

the other extreme; but what the world needs is cool, unbiased testimony from those who will, with unprejudiced pen, give the good and the bad points of all these things as they come up.

REPORTS ENCOURAGING.

THE UPS AND DOWNS IN BEE-KEEPING; \$265 FROM 17 COLONIES, AND 5 SWARMS MORE THAN SPRING COUNT.

I STARTED in 1886 with 17 stands; increased to 30, and sold 8 at \$5.00 each, before comb-honey time. I extracted 250 lbs., and secured 1250 lbs. of comb honey in 1-lb. sections. I received 15 cts. per lb. for the extracted, quick sale, and from 12½ to 16 cts. for comb, mostly 15 cents, by the case. My honey is mostly fall honey. My sale of bees and honey amounts to \$265, and I have 5 swarms more than I started with. That will pay all my expenses.

I want to say a little about how my bees have wintered. I usually put my bees in a row, close together, and set them on prairie hay and pack hay over them. I have had the best results. The bees always come out good and strong; but this spring I have a good mind to write "blasted hopes." The winter was very open, the bees flew about every two weeks. They have dwindled down badly. I lost six entirely, and the others are rather weak; but I have cleaned them all out, and am going to try to pull them through. I have been in the bee-business about ten years, on a small scale, but never before have I had such bad luck wintering bees. I had begun to think that Nebraska was the place to winter bees safely. F. C. LEFEVER.

Juniata, Neb., Mar. 21, 1887.

Thanks, friend L., for your report. I hardly see how you could think of putting yourself into Blasted Hopes. The fact that you wintered unsuccessfully last winter does not necessarily indicate that you will have poor success in the future. Considering how you made your bees pay, as indicated in the head of your article, your report ought properly to come under the head of Reports Encouraging, ought it not?

FIFTY-SEVEN DOLLARS FROM TWO SWARMS IN ONE SEASON.

Last spring I started with two swarms. They cast three swarms each. I saved five, one got away. I sold 487 lbs. of honey for \$57.24. I have seven swarms yet, all lively and strong. I make my own hives. My first swarm came off the 26th of May. They did not swarm, but made 108 lbs. of honey. My caps hold 28 one-pound sections. My bottom frames are the same width as the 4¼ x 4¼ x 1 15-16 sections. I ordered my fixtures from you last year. We have some flowers in bloom here now on the ground and on trees. I will send you one of the popple-blossoms. The bees work very strong on them. I have a great many linn-trees around me, and early cherry-trees.

Kimball, Mich., Apr. 16, 1887.

A. M. FRENCH.

AN AVERAGE OF 2½ LBS. OF HONEY FOR THE LAST 5 YEARS.

I wintered 42 colonies in a damp cellar this winter, at a temperature of 38 to 40°, with splendid results. All came out in good shape. They con-

sumed but very little honey. I averaged, last season, 145 lbs. of honey per colony, and 90 per cent increase. The last 7 years I have averaged 135 lbs.; and, taking out the 2 first years, my average has been 215 lbs., mostly extracted, with over 100 per cent increase each year. You may hear from me this season. The most snow this winter fell March 26th and 27th—18 to 20 inches on a level in the timber. Some of my hives were completely covered up with snow. I had a time in getting the snow out of the apiary. The ground is covered with snow, but it is going off fast. The bees were gathering honey and pollen yesterday and to-day, and the ground is covered with snow. Have you bees that can beat that? WM. MALONE.

Newbern, Ia., Apr. 3, 1887.

NOT A COLONY LOST OUT OF 300 PUT INTO WINTER QUARTERS.

Our bees at this date were never in better condition. They have lots of brood, and are strong in bees. We have not lost any yet in about 300 colonies. We wintered outdoors in a clamp, and about 100 in a bee-house, all in fine shape.

SMITH & JACKSON.

Tilbury Center, Ont., Can., Mar. 4, 1887.

11 TO 25, AND 1300 LBS. OF HONEY.

I will give my report for 1886. I started last spring with 11 swarms, and increased to 25 by natural swarming, and took 1300 lbs. of comb honey. I use a double-walled hive. The inside wall is made of rye straw. JOHN SHORT.

Moline, Mich.

REPORTS DISCOURAGING.

ALMOST A CANDIDATE FOR BLASTED HOPES.

I SEE that your department of Reports Discouraging is not very well supplied, so I send you a report. Last fall I started in to winter with 106 colonies of bees; 57 were in chaff hives; 49 were in Simplicity. All had a plenty of winter stores. The chaff hives had good chaff cushions in the upper story; the Simplicity hives had chaff division-boards at the sides, and were well packed with chaff above. Out of the 106 colonies, 56 are dead; 6 are queenless, and over 40 are weak. Out of the 49 in the Simplicity hives, 41 are dead; and out of the 57 in chaff hives, 15 are dead. The chaff hives will probably keep me out of Blasted Hopes.

This has been the hardest winter on bees in this locality since the winter of 1880. A good many beekeepers have lost all of their bees, and not over 20 per cent of the bees in this locality will "weather the gale." Unless the weather changes pretty soon, I may be able to give you a report for Blasted Hopes. Bark-louse nectar gathered late in the fall was what did the business for us. I shall be glad when Prof. Cook comes around with his bark-louse destroyer. GEO. A. WRIGHT.

Glenwood, Susq. Co., Pa., Apr. 19, 1887.

Your report is a little discouraging, friend Wright; but if it does nothing more, it demonstrates the very great superiority of chaff-packed hives over single-walled Simplicity hives for wintering. I don't think we ought to run the risk of trying to winter our bees in Simplicity hives. If the winter should be favorable you are all right; but if

it should be like the one you have just passed through, then you could have well afforded to buy chaff hives outright for all the colonies, instead of sustaining the loss you did. The winter in your locality must have been somewhat more severe than in most other places. As near as we are able to gather from reports, last winter, as a rule, was very favorable for wintering bees.

THIRD ATTEMPT AND THIRD FAILURE AT BEE-KEEPING.

This is my third attempt at bee culture, and my third failure, so I conclude to quit. I will relate my last start. Last fall I bought two colonies. They were not rich in stores, so I fed during the fall to each about 26 lbs. of granulated sugar. I bought two chaff hives, and transferred the bees into them. This spring the bees were in splendid condition. I began to notice that one came out several times on warm days, so I thought they had no queen. The whole swarm finally left for parts unknown, but it does not stop here. I find another swarm had robbed this one; and when they had cleaned it out they went for the other swarm, and now I have two empty hives for sale. L. ROTTMAN.

Benton, Ohio, April 13, 1887.

The old saying of "three times and out" seems to be verified in your case, friend R., but I hope you will not be discouraged yet. Your bees wintered nicely, but you allowed them to be robbed. You now have a stock of experience that will help you to be more successful hereafter. In your closing sentence you corroborate just what I said in regard to robbing, in my reply to friend Miller. Where the robbers succeed in using up one colony they are just in trim to pounce on and conquer one right beside it.

UNFAVORABLE FOR FLORIDA.

This has been the worst season I have known here. The pleasant weather came early, and this past month has been very unpleasant. I have not heard of any bees swarming this year.

Sorrento, Fla., Apr. 3, 1887.

N. ADAMS.

NOTES AND QUERIES.

DO VANQUISHED BEES HELP THEIR CONQUERORS?

I HAVE lost two colonies of my bees out of twelve. One of them starved to death, the other one was overpowered and robbed by a stronger colony. The battle-ground at the entrance of the hive showed signs of a desperate struggle. When discovered, the queen was dead, and the remainder (if there were any) were busily engaged in helping their victors to carry out the remaining honey. Do vanquished bees, after losing their queen, always help their conquerors?

Laura, Ohio, April 25, 1887.

R. W. BRANDON.

[Vanquished bees do frequently turn in with their conquerors and help carry the stores to the new hive. As good authority, however, as friend Doolittle has expressed doubts of this. It was several years ago through GLEANINGS; but so many reports came in at once, corroborating the matter, that I believe most if not all accepted it as truth.]

WHAT AN A B C SCHOLAR DID.

My spring count was 56; fall count, 70. I secured 1500 lbs. of honey, all comb, in one and two

pound sections. How is that for York State for 1886, and all through studying A B C and GLEANINGS?

To keep Clark's smoker-tube from filling with soot, tack a leather strap to the wide end of the bellows, and hang it up small end downward when warm, and the soot will run into the small end and can be dug out with a nail or small knife-blade when cold.

WALTER SEAMAN.

DeKalb, N. Y.

[Friend S., your point is an excellent one, and I have no doubt you are right; but supporting the smoker by standing it with the nozzle downward would, I suppose, answer equally well.

A WINTER REPOSITORY NOT SUCCESSFUL.

We always buried our bees in sandy ground, and they wintered well. Last fall we built a house 5 feet in the ground, 2 feet out, warm and nice; thermometer lowest, 32°. The bees were uneasy all winter. We put in 44, and now we have 20 weak ones. The building is 6½ by 20.

E. BUSH.

Schodack Landing, N. Y., March 28, 1887.

HOW TO GET RID OF ROACHES.

I saw an inquiry in GLEANINGS for April, for a method of getting rid of roaches. We were overrun with them. They came in empty berry-boxes from Philadelphia. I used powdered borax. It is a sure exterminator. Blow it in all cracks and crevices, and scatter it around where they hide in the day time. Bees have wintered very nicely in New Jersey the last winter, so far as I hear.

Hartford, N. J., Apr. 11, 1887.

E. J. LLOYD.

THE FELTON SWARMING-BOX.

Yes, Mr. Root, you got a very correct engraving of my swarming-box, except the handle, which you have got turned the wrong way. It should be turned with the long end down. Bro. Kaler says I have misrepresented his box. I have not done so intentionally. The Kaler box, as used in this country is held up among the bees when they are flying. For my part I should much prefer my own box; but opinions differ, and I do not intend to quarrel with Mr. Kaler.

S. E. FELTON.

Setley, Pa., April 8, 1887.

SEPARATORS, WIDE FRAMES, AND CASES.

I do not want any more wide frames at any price. I have been very much interested in separators, cases, and wide frames. I do not use separators, and have abandoned wide frames. I find cases much better. I make them out of ½-story Simplicity hives, with a honey-board. I am making the board of slats, with strips of perforated zinc let in between. I think that is good, and the case is also the best out. I can wedge them up, and they are fast and good. I sell my honey to stores principally, at 14 and 15 cts.

GEO. A. MATHEWS.

Katonah, N. Y., Mar. 23, 1887.

BEEES VERSUS SUNFLOWERS.

Will bees injure sunflowers by feeding on the pollen? One of my neighbors states that his sunflowers were injured by the bees. He counted 20 at once on some of them, and attributes their failure to bees. I tell him it was the dry weather.

JONATHAN TOWNLEY.

Elizabeth, N. Y., Apr. 12, 1887.

[You can assure your neighbor, friend T., that the bees can by no manner of means injure the sunflowers. Their visits, on the contrary, must be a benefit to every plant that produces seed.]

MYSELF AND MY NEIGHBORS.

Therefore shall her plagues come in one day, death, and mourning, and famine; and she shall be utterly burned with fire: for strong is the Lord God who judgeth her.—REV. 18: 8.

A LITTLE before the first of April I received a telegram from Prof. Cook, telling me to come and visit his sugar-bush. Now, there is one thing I like about these trips away from home. It enables me to learn more about the neighbors outside of my own immediate vicinity. It enables me to get a glimpse of this great teeming outer world that is now round about us on every side. But, dear friends, if my object in traveling were to find out objectionable features in humanity it would be a sad and sorry task, and I am going to try to tell of the good things to be found away from home, as well as bad things. One of the things that pleased me greatly on the cars of the Lake Shore road was the addition of a wash-room—or not exactly a room, but a little place set apart where plenty of soap, clean water, looking-glass, combs, and brush, were kept, so that they could be used by any one, whether he were able to pay for the comforts of a sleeping car or not; and I tell you, these utensils were used. During a ride of two hours to Toledo, there was scarcely a minute that somebody was not busy refreshing himself by a good wash. May God bless the railroad companies for thinking of this excellent feature to make the traveling public happy! My brother-in-law, Mr. Holmes, says they will probably make all the new passenger cars that way. If cleanliness is next to godliness, it is a good sign.

By a blunder of the ticket-agent at Elyria, I had, as I often do, got on the wrong route; but after the mischief was done, I began asking myself if God had not something for me to do on this route that I should not have found on the other one. At Toledo I found a train ready to step on to, providing I took a sleeping-car. The cars were new and exceedingly comfortable, compared with the crowded Union Depot, and when I asked the price of a sleeper to Holly, Mich., I was greatly surprised to find it was only a dollar; and it was a nice, pleasant-looking man who said it, in vivid contrast with some of the porters one sometimes meets. I went to bed at once, and slept soundly until I was told that Holly was at hand, at half-past four in the morning. The same porter pointed me to an excellent hotel right close to the station. Here I was to sit for four hours and a half. As it would not pay to go to bed again, I took a seat by the stove and commenced to read Prof. Cook's book on maple-sugar making; for, to tell the truth, I had never read it entirely myself, even though I was the publisher. Perhaps I might say here, that the hardest work of my life now is to read the books, letters, etc., that I really ought to read. I find, however, it is far easier for me to read such a book when I am away from home than when here; because here I have constantly to pull my mind off from one subject to consider other responsibilities, and then push it

back by force of will to the book I am trying to read.

My first interruption was from the clerk. In stepping outdoors he slipped down and tore two buttons off from his ready-made new suit, and he kindly offered me a cigar if I would sew the buttons on for him. At first I thought of declining the job as well as the cigar; but it occurred to me that I had better sew the buttons on, as it would give me some opportunity to get acquainted. He could not sew them on himself, because they were behind his back. I guess I did him a pretty fair piece of work, even if it was several years since I sewed on a button.

The next interruption was from a hack-driver who came in to wait for a train. Then an employe at the depot across the way came in, and, I presume, to find somebody to talk with, while he kept an eye on things across the track. The first salutation of the two was loaded with oaths and blasphemy; then they commenced a friendly talk, and I believe it was the worst talk I ever listened to in all my life. I looked at the young men and began studying as to how to give them a mild reproof in such a way as to do them the most good. As they went on, however, their lives seemed to be so widely separated from my own I could not think of any way to start a conversation without having them feel that I was a sort of crank, or somebody who wanted an opportunity of airing his piety. Very likely Satan was getting into my own heart as well as theirs. They had no tastes, no interests, in common with my own. The depot man, in speaking about keeping awake nights when it is necessary in the discharge of his duties, said that the only way he could keep awake was by keeping just about so drunk. When in that condition he was never sleepy at all. I wonder if the railroad company know that men they hire to fill responsible places are in the habit of propping themselves up during the night time—propping themselves up to a sense of duty and their responsibility, if you choose, by an abundance of whisky. The bare thought of it staggered me, and the words I had planned to use I put away, and I do not know but it was Satan who whispered that indignation was the only proper feeling to have for such as they. Pretty soon they began to sprinkle in obscenity with their blasphemy; then they began to tell impure stories; and while I sat feeling myself unable to cope with the worst language that I had ever thought or dreamed of, they went on from bad to worse. I kept my eyes on my book, but they must have been sharp enough to notice that I was listening; and for fifteen minutes I had such a glimpse of the possibilities in the way of the utter depravity of the human heart that I hope I shall never have again. I did not know then that human beings could be so lost to every sense of decency; nor did it occur to me that it was possible for anything in human form to descend into such fearful depths of every thing repulsive and even horrible, as did these two young men.

In the story of Ivanhoe, written by Sir Walter Scott, Rebecca, the Jewess, while

watching the warfare through the grate of her dungeon, says: "O great God! hast thou given man thine own image that it should be thus cruelly defaced?" The same feeling came into my mind—did God, when he created human beings in his own likeness, contemplate the possibility that they might descend to where these two were standing? I gave it up. The people were stirring, and the clerk had been kindling a fire in the parlor. I went in there and sat down, feeling helpless and discouraged. You may ask why I did not appeal to the clerk, whose buttons I had sewed on. I thought of doing so, but he was brushing out the saloon part of his establishment, and getting ready for the busy throng that was beginning to come. He evidently seemed to think their talk was all right and proper. May God forgive me if I got uncharitable just then. I went into a clean comfortable room, and sat in an easy-chair; but I was not easy, and I was not happy. I could not hear the filthy words from the other room, but conscience seemed to say, and keep saying, they were going just the same as if I were not there. Perhaps others had gone in to help them. And then I meditated, also, that such talk was probably going on, or, at least talk, of something in that line, in other railroad stations and public houses throughout our land—possibly in some parts of our own town of Medina. May God grant, however, that it is nothing nearly as bad, for the influence of our churches and prayer-meetings in Medina has now gone into almost every nook and cranny of our place, and I do not believe there are any so utterly lost around my home as those I found here; and this, too, in the progressive State of Michigan—the State I have for many years felt was almost taking the lead in intelligence and progress, and, I had hoped, in godliness. No wonder we have our prisons full, and our infirmaries full, and our insane-asylums full, while we are sowing such seeds and getting ready for the crop. Our text tells us that the outcome of this kind of sinfulness is plagues and death and famine. In the end, purification shall come by burning with fire: for strong is the Lord God who judgeth.

A few weeks ago a sample copy of an illustrated weekly came to our office. A simple glance at the paper showed that its purpose was to encourage every thing that leads to depravity and filthiness. In the back of the paper were advertisements of the vilest books and pictures that ever disgraced the civilization of the world. The advertisers admitted that the books could not be sent by mail, but that they must go by express. As it is a dangerous business even then, they were obliged to charge five dollars for a single copy; but in several places different venders guaranteed that said book should not be lacking one whit in the filthiness and vileness of its pictures that the same book had between thirty and forty years ago when the strong arm of the law tried to stamp it out of existence. An editorial note on the first page of the paper defies Christian people in their efforts to repress their vile sheet, and asks subscribers

to inform them promptly if any postmaster or anybody else tries to hinder it from going through the mails. As a matter of course, this paper attacks the religion of Christ Jesus. Their hatred and bitterness toward every thing pertaining to God's word crops out in every column. Ministers and superintendents of Sunday-schools, deacons of churches, or anybody else, and others of like character who have been led away by Satan, are hunted up, pictured out, and held up before the world with jeers, in the effort to make it appear that all professing Christians are hypocrites; that there is no purity, either in man or woman; and the deduction would seem to be that there does not need to be. In scanning its pages I fell to wondering what these people would have if they could have every thing their own way. Suppose the people of the ———, their patrons, keepers of grog-shops, managers of houses of ill fame, and all that crew, were put on an island by themselves, and left without law or restraint, to have things just as they liked, where would be the end? Does not our text tell the story?—plagues shall come in one day; death, mourning, and famine shall follow on. If you want to see the prophecy verified, visit your infirmary or insane asylum.

After I came home I told some of my experience at Holly at the noon service. Our stenographer and proof-reader, who also plays the organ, told me, as the service closed, that it was in the neighboring town of Howell, Livingston Co., a few miles west of Holly, where they threatened good men if they attempted to interfere with the whisky-traffic there; and threats were not all. The following telegram, under date of March 17, tells the story: "The business portion of the city is a mass of black ruins."

In talking with Prof. Cook, he told me that, if I commenced a warfare against the ———, I would have to take the chances of having my property burned; and he said that, in their own State of Michigan, anonymous letters had been sent to men who dared to stand up to their convictions of duty, threatening them with the burning of their stores and residences if they went ahead, and the amount of losses had been such as to make even good and brave men tremble.

Now, my friends, you may be somewhat surprised, perhaps, when I say that, after thinking and praying over this terrible problem that lies before us, I have come to the conclusion that we are almost all of us more or less guilty. If we have not started stories that savored a little of impurity, we have perhaps stood by and smiled, by way of encouragement to the teller, even if we have not said anything. We have heard such talk as I have mentioned, and have, like my poor self, been so startled and shocked that we have not even opened our mouths in protest. May God forgive my lack of courage! Some of us who are church-members, and, may be, deacons, have been in the habit of repeating things of this kind (when no women were around), just because there was something funny

about it or it was a rich joke. May be we have done it when a child stood by, or, say, a young man in his teens, or may be a young married man. Perhaps he has repeated it because he has heard it from Mr. So and So; and then it may be (but I trust but rarely) these funny things are passed about among the other sex. May God help us all to set a better example! Some years ago a new convert, a young friend of mine, and a boy who was trying, as I verily believe, to be pure in word as well as action—told me that a man in my employ was continually telling impure stories and jokes. This man was a professing Christian. I went to him about it, and he with downcast face admitted that he had got into the habit. I talked to him pretty severely, and was afraid he would be offended; but although he felt hurt, he did not resent it. Since then he has at different times thanked me, and assured me that the results of my plain but kind reproof had brought him nearer to the throne of grace. These things had begun to get between him and his Savior. Soon after, he came to our young people's prayer-meeting, and took part. My friend, you do not need to scan the columns of such papers as I have mentioned, to be sure that this thing kills spirituality from the heart of any man or woman.

To be continued next issue in Our Homes.

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

NO FOUL BROOD, AND EVERY COLONY WINTERED.

AS I had earnestly hoped, and so stated in the last issue, no colonies are lost by wintering up to date. I can hardly think this success is altogether attributable to a favorable winter, or to the chaff hive, though these two factors have a great deal to do in successful wintering. I am of the opinion, that the result in our own case was owing largely to the fact that we did the *very best we knew how*, knowing that the colonies were weak, and therefore needed special care if we expected to have any come out in the spring. Our apiarist, Mr. K., on account of the death of his father-in-law, was called away to take care of the farm last fall. This made it necessary for me to go into the apiary and give it more of my personal attention than formerly, at such spare hours as I could find from my work in the office. As it was impossible for me to do all the work as I wanted to have it done, I called upon one of our most trusty men to serve in the capacity of apiarist. We together, as our readers will remember, last year put the bees into winter quarters in the evening by lantern light and moonlight, and in the rain. Although Mr. S. had then had but little or no experience with bees, I knew that he would do just exactly as I told him. While I think there is a great deal of credit due to Mr. S. for the careful way in which he followed my directions, I think there is just a little credit due me for doing myself and telling him to do

just the right thing, in order that the bees might come out as they did. I make this broad statement, even at the very great risk of being called conceited (and I'd hate awfully to be called conceited), for just a little success. Is it not a thing to be a little "inflated" over, if you have wintered 200 colonies without the loss of a single one? To do it every season would be one of the "fine arts," and I don't aspire to that; but I do think, friends, that your success in wintering, whether it is a favorable season or not, is largely due to doing *the best you know how*.

LOTS OF BROOD, BUT NONE "FOUL."

We have had pretty fair weather for the last week or ten days. The maple-bloom is out, and the dandelions are showing their glad faces here and there over the lawns and through the apiary. As a consequence, brood-rearing has commenced in real earnest in all our colonies; and the downy young bees, so welcome in the spring, are dotting the combs as the latter are pulled out and examined to see whether they bear traces of foul brood. For three weeks now we have not had a sign nor a trace of foul brood, and we really hope that we shall have little or no more trouble from it. We think this result is largely owing to the fact that the two first colonies which had foul brood this spring were totally destroyed, so that not a single bee was allowed to escape and so get into other colonies. This might have been done by the starvation plan; and although we were entirely successful last summer in curing the colonies *themselves* which were diseased, we were not enabled to keep a few stray bees from entering and propagating the disease in neighboring hives. Our friend D. A. Jones says there is no need of letting these bees get loose and spread the disease, by the starvation plan. I presume not; but certain it is, that we did not succeed very well last season. Perhaps we were careless. At any rate, I think now if we had burned our first case of foul brood, even to the last bee, we should have had but little trouble.

THAT SMOKER SAWDUST FUEL.

A few days ago Mr. S. told me that he had just learned how to use that kind of sawdust fuel so as to make it last and give good smoke for four or five hours, without refilling the smoker. Now, dear friends, if any of you have tried to use this sawdust fuel as I described in this department last year, on page 550, and failed, please keep on trying if you want to save a good many hours' time.

OUR SWAMP APIARY.

As it would be hardly safe or wise to fill orders from our home apiary, although we are beginning to believe foul brood is cured, we thought best to locate another apiary. We have accordingly selected our peat swamp. Ten colonies purchased of an A B C scholar are already there, and we are expecting a couple more loads of bees from friends Rice and Shook, of Seville, some 10 miles from Medina. Orders for bees and queens will be filled from the "Swamp Apiary" and from Neighbor H.'s two apiaries. Our friends will not, therefore, need to fear foul brood if they purchase of us.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, MAY 1, 1887.

Blessed are the pure in heart, for they shall see God.—MAT. 5:8.

OUR subscription list is growing at a sure and steady pace. We have at date 7155 subscribers—a gain of 250 within the past month. This is 11 higher than we ever had before at any time. Many thanks.

ANOTHER CANADIAN BEE-JOURNAL.

THREE numbers of the *Canadian Honey-Producer*, by our old friends E. L. Gould & Co., Brantford, Ont., Can., are at hand. The journal is well gotten up, and the matter is valuable—certainly worth more than 40 cts., the price asked, to any one who has time for more reading. The only thing that troubles me is, will the people of Canada support another bee-journal? It seems sad to me to think of the number that have been started in the United States, only to live a few months or a few years. These journals all seem to be worth all the money asked for them; but the field for periodicals, especially class journals, is constantly overworked.

ECHINOPS SPHEROCEPHALUS.

A WRITER in the *British Bee Journal* of April 14th does not speak very favorably of the Chapman honey-plant. He says that it is grown in England as an ornamental shrub, is easily cultivated, and in any well-ordered garden it can be kept within bounds. It would seem that the plant in England is liable to spread and make trouble. The same writer says, further, "We do not recommend its extensive cultivation, for it is useless as a fodder-plant, and we doubt if it will answer to grow for honey alone." By the way, have any of the friends ever tried putting a paper sack over a common thistle to see if it would secrete nectar enough during the period in which it was covered by the sack (24 to 48 hours) to be almost dripping with the raw honey, as is the case with the Chapman honey-plant?

PRACTICAL TURKEY-RAISING.

THE above is the title of a very neat, pretty little work giving full and complete directions for raising turkeys. It is written by no other than the well-known writer on poultry, Fanny Field. We have not had time to review it thoroughly; but from turning over the leaves and reading here and there a paragraph, we feel sure that it is just about the thing for those who contemplate or who do make a business of raising this savory product for Thanksgiving dinners. The author has had great success in all departments of poultry-raising, and is well known as a practical writer among those who are interested in fowls. In turning over the first few pages, we find discussed, "Will it Pay?" "Tur-

key-Raising for Women," "How Much Profit for Heft?" "Capital to Begin With," and so on. The book can be obtained of the publisher, R. R. Mitchell, 69 Dearborn St., Chicago, Ill. The price is 25 cents.

GOVERNMENT PAMPHLETS ON CARP AND CARP-PONDS.

We have just received three different pamphlets, each one nearly the size of our book on carp culture, and to me they are intensely interesting. I wrote at once to the commissioner, Mr. S. F. Baird, asking if they were prepared to furnish them free to all applicants, and below is his reply.

C. S. Commission of Fish and Fisheries,
Washington, D. C., Apr. 25, 1887.

There will always be one or more kinds on hand for free distribution to whoever makes personal application therefor. You can direct people to write to the commission for all necessary information upon carp culture. S. F. BAIRD,
Commissioner.

DATING PRINTED MATTER.

NEVER publish a price list, circular, tract, or any thing else, without having the date with it. Many times it is of the utmost importance to know just when a document was sent out; and in regard to new inventions, a circular without the date of its publication amounts to just nothing at all in the way of evidence. In our notices of price lists and circulars received, of course we do not want to notice the same thing year after year; and as we have no means of knowing this except by looking at the date, I hope the friends will excuse us for refusing to notice a circular or catalogue unless there is some date on it to tell when it was printed. In this day of progress we can not afford to waste our time reading something that was printed long ago, and is away behind the times; besides, everybody has a right to know just when each new thought was first given to the world.

LONG LETTERS.

"THE hardest task now before me in life is to read the things I ought to read. I have been obliged to stop reading books entirely—even the new ones that have just come out on my favorite subjects. I glance them over and look at the pictures, and sometimes read a page or two here and there, but pretty soon I am compelled to lay it aside, oftentimes with a sigh, saying to myself, "This is all the time I dare give this one." Even the books on carp and carp-ponds, mentioned above, that are issued by the Government, have to be glanced over in the same way. I try to read most of the letters that come to me; but where there are several pages, all I can possibly do is to glance over it and hand it to somebody else, instructing them to give it the attention it ought to have as well as they can, and then I take up the next one. And I can not follow even this very long at a time or my reasoning powers would break down. I mention this, dear friends, to let you know that, if you write very long letters, the probability is I shall not be able to read them, and you see you thus defeat the object you had in view; namely, you get less of my attention than had you written more briefly. Articles for GLEANINGS, if very long, are handed over to Ernest.

A SURPLUS CASE FOR COVERING THE EXPOSED PARTS OF THE SECTIONS.

J. W. POWELL & SON, Mankato, Minn., sent us a surplus arrangement, the distinctive features of which are slats so arranged as to cover the tops and bottoms of the sections, leaving only the side edges and the inside of the sections exposed to the

bees. Mr. Shuck has invented a super somewhat similar to this, but, unlike Mr. Shuck's, Powell & Son have theirs so arranged that the sections may be quickly uncovered. They ask us if we should not prefer this to a T super. In answer, we would say that we do not. The slats in the Powell & Son's case, covering the top and bottom sections, come directly in contact with the sections. If we are correctly informed, it is just such interstices as are made by this kind of an arrangement that the bees fill with propolis. We should very much prefer the Moore crate or the T super, used in connection with the Heddon slatted honey-board. The T super arrangement leaves very few crevices, comparatively, for the bees to fill in with propolis. It seems desirable to have a bee-space above and a bee-space below the sections, *without any thing intervening.*

A BEE-BOOK IN THE SWEDISH LANGUAGE.

OUR friend HJ. Stalhammar, who has translated the Potato-Book into the Swedish language, has written a book on bees, the title of which is "A Practical and Theoretical Treatise on Bee-keeping." The book contains 182 pages, and is copiously illustrated. We are sorry to inform our readers that our "Swedish editor" is at present away on a journey, hence we can not give a very detailed description of the contents of the work; but as nearly as we can judge from the engravings, we should say that the author has collected his ideas from various sources; for instance, in the scientific part we notice some of the engravings which have appeared in Cook's "Manual of the Apiary" and Cheshire's "Bees and Bee-keeping." In the practical part we notice engravings of American, English, and German hives, and we have no doubt the author has given due credit in all cases. It is evident, also, from the engravings, that the writer has taken pains to select the cream of the literature on bees, and has carefully compiled them all into one work. It will be a valuable book for Swedish-speaking people. It is published at Goteborg, Sweden, but the price is not stated in our money.

WANTED, REPORTS DISCOURAGING.

SOMETIMES we are accused of printing only the bright side of bee-keeping. We have long had a department of "Reports Encouraging," together with occasional "Reports Discouraging;" and where the writers so desired it we inserted their letter under the head of "Blasted Hopes." To be fair with our readers, and give them the dark as well as the bright side of bee-keeping, we solicit reports of a discouraging nature; and if you have had "awful bad luck," and feel about ready to give up the business, write us a letter for Blasted Hopes. If, indeed, the candidates for the Reports Discouraging and Blasted Hopes departments are growing less for want of patronage; and if, indeed, the science of apiculture has so far progressed that we can now expect and hope for uniform success, then we can attribute this state of affairs largely to the bee-journals and books. To be sure, personal skill would be no small factor to take into consideration. In the heading we have said, "Wanted, Reports Discouraging." We are sure that none of us desire to see them; but if there is any considerable number who have had poor success within the last year, either in wintering or from drought, let us have the doleful story. Perhaps we can help you out of your trouble.

ENGLISH GUIDE-BOOK PAMPHLETS.

FROM Thomas Wm. Cowan, editor of the *British Bee Journal*, we have received Nos. 1 and 2 of a series of guide-book pamphlets. No. 1 is entitled, "Doubling and Storifying for Extracted and Comb Honey, and the Prevention of Swarming." No. 2 tells "How to Make an Extractor and Bellows Smoker." In the former, the author, Mr. Cowan, gives some plain practical directions on the production of honey. The term "doubling and storifying," as used by our English friends, is, we presume, about synonymous with our word "tiering-up." He recommends only simple and inexpensive hives—those that will "tier up." He very sensibly discourages the use of frames with side supports for spacing frames for fixed distances. We notice in the advertisements of the *British Bee Journal* that a good many are advertising this kind of frame. In reference to this point, Mr. Cowan says, "Our frames have neither distance-guides, pins, nor projecting shoulders; we can bring them closer together, or put them further apart, as we wish, without any difficulty. It is many years since we discarded all these encumbrances, and we have never had reason to regret it." Mr. Cowan also emphasizes the importance of having only one size of hive and one size of frame. His method for storifying, or, as we term it, tiering up, is such as is practiced by our most successful bee-keepers here in America. This little work, "Doubling and Storifying," may be had for the modest sum of 3 pence, or, in our money, postage included, probably 10 cts. "How to Make an Extractor and Bellows Smoker" may be had for 6 pence. Both of the above are published by J. Huckel, Kings Langley, Herts, England, of whom they can be obtained.

HOW TO KEEP DIFFERENT VARIETIES OF POULTRY PURE WITHOUT GOING TO THE EXPENSE OF FENCES.

MAY be it won't suit your case, but I will tell you how it answers here. Friend John C. Capehart, of St. Albans, V. Va., sent me a beautiful trio of Silver-spangled Hamburgs. They are not only everlasting layers, but they are also everlasting flyers. One day I happened to look up and was astonished to see a bird of beautiful plumage hovering over the factory. She sailed down at my feet, and proved to be one of the Hamburg pullets. So you see that making a fence for these is out of the question. I tried a sitting of eggs, hoping they would be mostly pure; but the chickens had feathers on their toes, and bore other unmistakable evidences of relationship to our ten-dollar Brahma rooster. If I fenced them up, the fence must be covered with netting at the top as well as the sides; but I could not bear the thought of cooping up the graceful little fellows, so I carried them down to the carp-pond and kept them shut up three or four days. They are now roosting in a beech-tree nights, and the pullets are laying beautiful white eggs in a brush-heap under said tree day times. What food they need, besides what they gather, I place in a box after dark, under the beech-tree. Thus you see I have been working on the Stoddard egg-farm plan. They never follow me up to the house or barn, because they do not know that I have any thing to do with the supply of food. The carp-pond is so far away from the barn that the other fowls do not often get down there. As to how many different breeds could be kept in this way on ten acres, without mixing, is the problem.

SPECIAL NOTICES.

MAPLE SYRUP.

THAT nice maple is not all gone yet. Remember, we mail samples of the two kinds to any one on application.

SPECIAL NUMBERS OF GLEANINGS WANTED.

We will pay 10 cents each for a limited number of April 15th GLEANINGS for 1884. Be sure not to send any other number. Remember the date.

SUNFLOWER-SEED FOR FEEDING POULTRY.

We can furnish a nice article of plump seed, but not quite as large as the Mammoth, for 7 cts. per lb.; 10 lbs. for 60 cts.; 100 lbs. for \$5.00. There are about 40 lbs. in a bushel.

FIVE-CENT ROUND-POINTED SCISSORS.

We are unable to get any more of the five-cent round-pointed scissors, made of steel wire. We have some very nice ones, however, the same as we formerly had, made of metal. They are much handsomer, if not quite as strong as the ones made of steel wire.

PLANTS OF THE FIGWORT, OR SIMPSON HONEY-PLANT.

THOSE who have failed to get good plants by sowing the seed can be furnished with good strong roots which can hardly fail to grow and give blossoms this year. Price for one root, 5 cts.; 10, 25 cts.; 100, \$1.25; 1000, \$10.00. If wanted by mail, add 2 cts. each extra for postage and packing.

RASPBERRY-PLANTS.

We can furnish honey-bearing raspberries, if orders are sent in at once, before cultivating. We can furnish roots of either Cuthbert or Gregg raspberry-plants, at the same figures given above for the figwort. The Cuthbert and Gregg we consider the leading sorts for fruit, and the Cuthbert is especially the bee-plant.

THE SMITH IMPROVED FORCE-PUMP ADVANCED AGAIN.

We have just received a shipment of the Smith improved force-pump and sprinkler, illustrated on another page in this number. The improvements are all in the plunger. The lower end, instead of being wound with cotton tow, has a band of leather, which will work much more easily, and last much longer. The upper end of the handle has a round knob instead of the old handle, and is painted red. The plunger is turned the same size from top to bottom, and runs through a wooden plug that fits into the top end of the barrel. All these improvements have cost the manufacturer so much that he is obliged to advance his price again. We can furnish you them at his wholesale price to jobbers, which is as follows: Single pumps, \$1.00 each; three for \$2.75; crate of one dozen, \$10.00; two dozen, \$18.00; four dozen, \$33.00; eight dozen, \$60.00; twelve dozen, \$84.00. They are all put up in crates of one and two dozen each. The plungers come inserted in the pumps, instead of being in a separate crate as heretofore.

THE 32D THOUSAND OF THE A B C BOOK JUST OUT.

The last 5000 of the A B C book for 1886 was sold in just about a year's time, and in order to get the edition for 1887 out just as the former edition was exhausted, we were obliged to run our press night and day. We are happy to say to our readers that the present edition has received a more thorough revision than any previous one. Not only has a great deal of new matter been added, but many new and fine engravings have been inserted in the context. Almost every subject in the whole work has received more or less changes to suit the advancement of the times. Some of the subjects have been entirely re-written, so changed is the progress of apiculture. The work is now virtually as near up to the times as if it had been entirely written in the year 1887. As you are perhaps aware, the whole work is kept in standing type, so that a single letter, word, paragraph, or whole pages, can be stricken out or modified as the true spirit of advancement dictates. The price of the A B C will remain the same as formerly.

FULL COLONIES OF ITALIAN BEES

With queen, in A. I. Root's Simplicity hive, 9 metal-cornered wired frames, combs drawn from full sheets of foundation, \$5.00. I make this offer to reduce my stock of bees in a short space of time, as other business demands my attention. 89d

1000 FIRST-CLASS SMOKERS, CHEAP.
E. T. LEWIS & CO., Toledo, O.

PASTEBOARD BOXES

FOR ONE-POUND SECTIONS OF

COMB HONEY.

THIS box has a bit of "red tape" attached to it to carry it by. It makes a safe package for a single section of honey for the consumer to carry, or it can be packed in a trunk, if he wants. It can be opened in an instant. The price of the box is 2 cts. each, set up; in the flat, 15 cts. for 10; package of 25, 30 cts.; \$1.00 per 100; or \$9.00 per 1000; 10,000, \$80. If wanted by mail, add \$1.00 per hundred for postage. Colored lithograph labels for putting on the sides, two kinds, one for each side, \$3.00 per 1000. A package of 25, labeled on both sides, as above, 50 cts. By mail, 30 cts. more. They can be sold, labeled on one side or both sides, of course. We have only one size in stock, for Simplicity sections. Sample by mail, with a label on each side, 5 cts. If you want them shipped in the flat, labels already pasted on, the price will be ten cents per hundred for putting them on.

Your name and address, and the kind of honey, may be printed on these labels, the same as other labels. The charge for so doing will be 30 cts. per 100; 250, 50 cts.; 500, 75 cts.; 1000, \$1.00.

A. I. ROOT, Medina, Ohio.

JOB LOT OF POULTRY-NETTING.

Small Pieces at same Rate as full Rolls—1 ct. per Square Foot.

Two or more pieces, 5 per cent off; ten or more, 10 per cent discount.

You will notice in this lot some with heavier wire than No. 19, and some with smaller mesh than two-inch. Both of these are worth more at regular prices than two-inch No. 19; but as it is a job lot we put it all in at the same price.

60	2	19 586, 490, 445, 385, 330, 330, 325, 285, 280, 240, 225, 230, 210, 180, 165, 160, 140, 130, 80, 50.
60	2	18 410, 335, 320, No. 17 wire, 195.
72	1 1/2	19 438, 312, No. 18 wire, 228.
72	2	19 750, 730, 690, 672, 636, 618, 558, 510, 438, 438, 420, 270, 252, 252, 222, 192, 168, 168, 162, 162, 156, 156, 156, 120, 66, 48.

We know of nothing nicer or better for a trellis for creeping vines than the above netting. The 12 to 24 inch is just the thing to train up green peas, fastening the netting to stakes by means of staples. If the stakes are set in substantially, one each 12 or 15 feet will answer. When the peas are stripped off the stakes, netting and all can be rolled up and laid away until another season.

POTATO BOXES

(TERRY'S).

These are made of basswood, bound with galvanized iron. The galvanized iron gives strength, and the basswood strength and lightness. These hold exactly a bushel when level full, and may be piled one on top of another. Although they are made especially for potatoes, they can be used for fruit, vegetables, picking up stones on the farm, and a thousand other purposes. When piled one above the other, they protect the contents from the sun and rain; and from their shape a great many more bushels can be set into a wagon than where baskets are used. They are also much more substantial than baskets.

Price 25 c each; 10, \$2.25; 100, \$20.00. In the flat, including nails and galvanized iron, \$1.75 for 10; 100, \$16.50; 1000, \$150.

A. I. ROOT, Medina, O.

Cash for Beeswax!

Will pay 20c per lb. cash, or 23c in trade for any quantity of good, fair, average beeswax, delivered at our R. R. station. The same will be sold to those who wish to purchase, at 25c per lb., or 28c for best selected wax.

Unless you put your name on the box, and notify us by mail of amount sent, I can not hold myself responsible for mistakes. It will not pay as a general thing to send wax by express.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is often times quite an accommodation to those who can not afford higher-priced ones.

A goodly number of black and hybrid queens for sale; hybrid, 40c; black, 20c; mismatched, 45c.
W. G. HAYEN, Pleasant Mound, Ill.

We can furnish a few hybrid queens at 50c each; also black or Tar-bee queens at 25c each. Apply to
8d SYKES & WILLIS, Elizabethtown, N. C.

I have three black queens in my apiary that I shall remove before long. Italians are to take their place. Who wants the three for 50 cents?
C. F. GUNN, Jubilee, Davidson Co., N. C.

I have a lot of hybrid queens for sale; price 50c in April; May, 2 for 75c. Safe arrival guaranteed.
H. M. MOYER, Hill Church, Berks Co., Pa.

FOR SALE.—Several hybrid queens at 50c each, by mail.
PELHAM & WILLIAMS,
Maysville, Mason Co., Ky.

FOR SALE.—Mismatched Italian queens in May, 45c each; June, 40c. Twenty on hand and will have more soon. Prompt shipment. Safe arrival and satisfaction guaranteed. S. H. COLWICK,
Norse, Texas.

SECTIONS.

I will sell nice white basswood sections for \$3.00 per 1000, smooth on both sides, 4 piece all dovetailed, 4 1/4 x 1 1/4. Send for sample.
7tfdb W. S. WRIGHT, Battle Creek, Mich.

GLEANINGS AS AN ADVERTISING MEDIUM.

Eighty-six tested queens have been mailed. All were heard from but five. There has been no loss this spring. Accept our thanks for the adv't. It will bring the hundred dollars. Next year, God permitting, 200 queens will be ready in April, for \$1.00 each.

J. W. K. SHAW & CO.
Loreauville, Iberia Par., La., May 2, 1887.

MORAL PATENTS.

The following very kind letter from Norman Clark, the inventor of the smoker bearing his name, is at hand, and we here give it to our readers:

Friend Root:—Last evening our pastor's subject was "The kindness of kindness," and he closed something like this: In earlier days, there were men who roved the world over to find that which would give perpetual youth. In these latter days many find it, and it is those who have Christian charity, who have sympathy for all; who love their neighbors as themselves.

Thanking you again for being so thoughtful of me, I remain very truly yours,—
NORMAN CLARK.
Sterling, Ill., Apr. 25, 1887.

Attached to the letter is a receipt. It reads, "Received of A. I. Root one hundred dollars, a gratuity on smokers, and for which I thank you."
NORMAN CLARK."

KIND WORDS FROM OUR CUSTOMERS.

PAID FOR ITSELF THE FIRST DAY.

The goods you sent us are here, and give entire satisfaction. The machine for fastening fdn. in sections is a fine thing, and paid for itself the first day used. We should not want to do without it.
Mazo Manie, Wis. W. A. JOHNSON & BRO.

ONE WHO LIKES THE CLARK SMOKER.

Clark's smoker is the most perfect of all smokers I ever saw; is the easiest handled, and gives the strongest draft of all smokers. I would not do without it for the price of five smokers. I have been keeping bees for the past nine years, and have decided that tobacco smoke is injurious, both to bees and myself. Often, after taking honey from the hive, I notice that many bees become sick and die, caused by strong tobacco smoke, and I have often been sick myself from smoking.
Manilla, Ind., Apr. 30, 1887. G. E. HAWKINS.

THE HOME TALKS EXERCISING AN INFLUENCE.

I should like to tell you in what esteem your Home Papers and neighborly talks are held. If there were nothing in GLEANINGS but Our Homes I should take it for the influence your talks have with me. I feel that the principles of your talks are permeating my life, and I know that my conduct with my fellow-men is favorably influenced by the ideas advanced in your familiar home-like talks. Our Homes in Mar. 15, especially, touched a tender spot in my heart, for it is now but a year since I parted with a dear and only brother, the loss of whom I could not for a long time become reconciled to. But I wish from experience to corroborate your talk and consolation to the friend referred to.

For some time after my bereavement this prayer was almost continually in my mind:

My God, my Father, while I stray
Far from my home, on life's rough way,
Oh teach me from my heart to say,
Thy will be done.

Next came the hymn beginning,

Jesus, lover of my soul,
Let me to thy bosom fly.

I can truly say, that in Christ alone is consolation and help in these times of trouble. I believe these afflictions are ordained to wean us from the world; for as one by one we lose our dear friends, those whom we are living and working for, we of necessity transfer our affections from earth to heaven; for it is written, that "where the treasure is will the heart be also." I hope you may be spared many years to point the straight and narrow way that leads to life.
C. W. COSTELLO.

Waterboro, Maine, Apr. 24, 1887.

YES, I WILL

Devote my time exclusively to rearing pure Italian queens. If you know my strain, send me your orders; if not, send me a stamp for samples of live workers. Untested queens, \$1.00 each; \$9.00 per dozen. Tested queens, \$1.50 each; \$15.00 per dozen.
tdtb
THOMAS HORN,

Ark. or big brown, and pure Italians mated with brown drones, 20 to 60 cents each; ready now and through swarming season. 10tdtb
SALLIE MORROW, Wallaceburg, Ark.

A Barometer for Gardeners and Farmers.

We have finally succeeded in getting a wonderfully pretty little aneroid barometer that we can sell as low as \$2.50. One of them has been carefully tested by the side of our mercurial barometer, and it follows the rising and falling of the mercury with wonderful accuracy. It seems to me that these little instruments ought to pay for themselves over and over again for any farmer or gardener, or any person who is dependent on the vicissitudes of the weather. The instrument much resembles a pretty little clock, and it may be sent by mail safely for 10 cts. extra for postage. You will remember that my method of using any barometer is to pay little or no attention to where the indicator or mercury stands. When you wish to know what the weather will be, tap the instrument with the end of your finger. If the indicator (or mercury) falls, there is a prospect of rain; if it rises, you are pretty safe in deciding there will be no rain very soon. If a considerable storm is approaching, the mercury will keep falling for some hours, and it will drop a little every time you touch it, even though you tap it as often as once an hour. When it keeps dropping for several hours, look out for a storm or a big wind. If it keeps rising for several hours, go on with your work and you will very seldom be misled.
A. I. ROOT, Medina, O.

BEES CHEAP!

I have had charge of A. I. Root's apiary for three years. I intend to start an apiary five miles from town; will sell full colonies and nuclei cheap. Fine queens a specialty. For particulars, address

❧ A WHEELBARROW ❧ FOR ❧ BEE-KEEPERS. ❧

ALSO A WHEELBARROW FOR WOMEN, CHILDREN, AND
PEOPLE WHO ARE NOT VERY STOUT.

OUR 35-POUND WHEELBARROW, CAPABLE OF CARRYING 500 POUNDS.

them at their convenience, when times were dull. Well, friends, the wheelbarrows are here, and they are a surprise to everybody. We show you a picture above. We have two sizes—the smaller one weighing only 35 lbs., and yet it will carry 500 lbs. safely, and it can be packed so closely together for shipment that you can take the whole thing under your arm and walk off easily. The wheel has flat spokes instead of round. The different pieces are all cut and forged by means of dies. The legs are steel, so they will neither break nor bend, even if you bump them on the sidewalk. The springs are oil-tempered, with adjustable bearings, so you can tighten them up for wear. More than all, the wheelbarrows are the nicest job of painting and varnishing, I believe, I ever saw, for a farm implement. They are handsome enough to go around town with, and strong enough to do heavy work; and yet the price of the small size is only \$4.00, the same as our iron wheelbarrow. The larger size is \$4.50. The only discount that can be made is 5 per cent off for two; 10 per cent off for five, or 15 per cent off for ten or more. They can be sent either by freight or express. It is only five minutes' work to put one together.

A. I. ROOT, Medina, Ohio.

E. M. HAYHURST'S FINE ITALIANS.

\$4.50 TO \$5.50 PER COLONY.

On account of ill health I have decided to sell my **Queen-Yard** this season, at the following prices: One full colony, \$5.50; two or more, \$5.00 each. These bees are in one-story, ten-comb Langstroth hives; have fine young tested queens, and a good amount of brood and bees, with honey for the trip; are perfectly healthy, no foul brood in my yard or neighborhood; they are extra fine stock, and first-class honey-gatherers. If wanted in rough shipping-box instead of hive, the price will be 50 cts. per colony less than above. Safe arrival guaranteed. Will begin shipping about May 1st.

HONEY COLUMN.

CITY MARKETS.

NEW YORK.—*Honey.*—The sales of comb honey the past two months exceed largely sales of corresponding time last year. The large stock in dealers' hands is becoming less every day, and the present outlook is, that all the best grades will be closed out before the new crop arrives. There is quite a large stock of dark and off grades of white, which we apprehend will be carried over. Prices are ruling low. We quote as follows.

White comb honey	9@12
Dark " "	5@7
Cal. " "	8@9
California extracted	5@6
Beeswax.—23@24½.	

We beg to inform bee-keepers through your valuable journal of the removal of our place of business as below, where we have better facilities for handling honey, and respectfully invite all beekeepers visiting our city to give us a call. Yours truly,
MCCAUL & HILDBRETH BROS.

May 10. 28 and 30 West Broadway, near Duane St.

MILWAUKEE.—*Honey.*—The demand continues very good for honey in this market, and values remain unchanged on all grades below the very finest, and we will now quote market firm.

Finest white 1-lb. sections	12@12½
Choice " 1-lb. "	11@12
" " 2-lb. "	10@11
Dark not wanted, and imperfect slow.	
Extracted, finest, white kegs	6¼@7
" " white, good, kegs or bbl.	6@6½
" " dark	4@4½

Beeswax.—25c. A. V. BISHOP,
May 4, 1887. 142 W. Water St.

DETROIT.—*Honey.*—There has been more inquiry for comb honey of late, and the stocks of honey on hand will be nearly all disposed of before the new crop. Best comb honey, 11@12 in 1-lb. sections.

Beeswax, 23@24c. M. H. HUNT,
May 12, 1887. Bell Branch, Mich.

CLEVELAND.—*Honey.*—The market is clearing up nicely in honey, with prices unchanged. Best white 1-lb. sections, 12@13. Second, quality 10@12. Buckwheat dull at 8@9. Extracted, 5@6.

Beeswax.—25c. A. C. KENDEL,
May 10, 1887. 115 Ontario St., Cleveland, O.

NEW YORK.—*Honey.*—We report market dull. There is a limited demand for buckwheat comb honey; and if it continues the market will soon be bare of all comb honey. We quote:

Buckwheat and dark, 1-lb., 6@7; 2-lb., 5@5½.
We advance price on California extracted, and now quote 5½ in jobbing lots.

May 11, 1887. THURBER, WHYLAND & Co.,
New York.

PHILADELPHIA.—*Honey.*—Honey nominal, and same as last reported.

Beeswax, steady. Choice yellow, 22@23; dark, 20; white, 27. PANCOAST & GRIFFITHS,
May 10, 1887. 242 South Front St., Phila.

BOSTON.—*Honey.*—1-lb. best, 14; 2 lb. best, 12; extracted, 5@7.

Beeswax, 24c. BLAKE & RIPLEY,
May 10, 1887. 57 Chatham St., Boston.

CHICAGO.—*Honey.*—Honey is selling slowly with the best white 1-lb. sections bringing 12c in a small way. 2-lb. about 8c; and dark 7c. The offerings are not as large by half as last month, and it looks as though the crop was mostly in sight. Extracted honey, 4@6.

Beeswax, 25 for yellow. R. A. BURNETT,
May 10, 1887. 161 South Water St., Chicago, Ill.

I have a barrel of nice well-ripened candied honey, medium light in color. I think it is principally white clover, as we have so much growing all around here. I will take 8 cts. per lb. for the honey of any one who will take all of it, and I will put it on the cars at our nearest station, purchaser to pay the charges after it is put on the cars.

MRS. H. F. BARGER,
Border Plains, Webster, Co., Ia.

A CASE OF HIBERNATION.

AN IDEAL CELLAR FOR WINTERING BEES, AND HOW IT HAS WORKED FOR THE PAST THREE YEARS.

A YOUNG man, resident about 50 miles from here, whose apiary I visited the other day, has, I think, solved the hibernation problem, so far as cellar wintering is concerned. He has been quietly studying apiculture for some years past, and three years ago last fall he built a cellar for bees on the most approved principles he could gather from the experience of the best bee-keepers, as recorded in the bee-journals. The result is, that he has wintered his bees for three successive winters, practically without loss. When I visited him the other day he had about half his colonies set out on their summer stands, and we looked most of them over. They were in fine condition, some of them were overflowing with bees. One colony, on four frames, which he did not expect to survive, were in good shape, and, in his judgment, were stronger than when set away in the fall.

There were about 250 colonies in the cellar, all told. With half of them removed, the thermometer stood at 52°; it had ranged from 52 to 58° all winter. Yet at this high temperature the bees maintained perfect quietude. Not more than five pounds of honey per colony had been consumed, on the average.

I call this a case of hibernation, from the stillness that reigned in the cellar, the small amount of stores consumed, and, I may add, the fewness of the dead bees to be seen on the cellar floor, which had not been swept at the time of my inspection. I am sure that, had the bees been very active, and

exposed to a lower temperature, they would have consumed far more honey, and there would have been a larger number of dead ones on the cellar floor.

All who read this will want a description of the cellar which has proved such a suitable winter home for these bees. It is about 18x20 in size, walls 10 feet high, and built of stone. A railway runs through the farm on which this apiary is kept, and from a deep cutting there is a sub-earth air-duct, 200 feet in length, made of 10-inch drain-tile, which supplies fresh air at the temperature of the earth away below frost. A pipe for the escape of foul air runs up from about the middle of the cellar, and is connected by an elbow with the kitchen cooking-stove. The bottom of this pipe spreads out into a flange 3 feet in diameter, and is supported on 4 bricks set edgewise. There is a wooden pipe on each side of the cellar for the escape of hot air. These are set in the wall, about 7 feet from the floor. The escape is through a six-inch hole cut in the horizontal top of each pipe. Outside there is an elbow, and the end projects a couple of feet above ground. Through one of these pipes, which was open at the cellar end, there was a perceptible current of warm air at the time of my visit. Several times, during mild spells in winter, these pipes had been used to prevent the inside temperature becoming too high.

Evidently, this cellar worked like one huge hive. Factory-cotton quilts only, covered the bees. The cellar is a very dry one, the earth on the floor being in a state of dust, and the dead bees, what few there were, dried up, their bodies making an audible crackle when you crushed them with the foot. There was no cellary smell perceptible. The air was as fresh and sweet as could be desired.

If I had the conditions of outdoor wintering as clearly demonstrated as they are for cellar wintering, I should rejoice. But there are still some points that are dubious to my mind. These, however, I will reserve for discussion some other time.

WM. F. CLARKE.

Guelph, Ont., Can., May 2, 1887.

Very good, friend C. The only difficulty in the way of a perfect understanding in the matter of hibernation is the definition of terms. It does not seem as if we ought to call the case mentioned above, strictly hibernation. The Indian story, however, on page 343, I suppose might be called hibernation and nothing else, for the bees were, in that case, stiffened by cold until they were apparently lifeless. They were then put into the cave and kept in this stiffened, motionless condition through many months of winter, to be waked up again when the flowers bloomed. We are glad to get the good report in regard to sub-earth ventilation.

UNSEALED CELLS IN SECTIONS.

IS W. F. CLARKE'S BEE-STING THEORY OF THE NEW USE OF A STING SUPPORTED BY FACTS?

IN reply to friend Doolittle (GLEANINGS, p. 123), if honey is always cared for as he directs, it may be just as well to have some cells left unsealed in sections, *providing* the honey has the same care afterward. But after he has ripened these unsealed cells till there is no danger of their running, if those sections are left in a store or in some purchaser's pantry, will not these unsealed cells attract moisture much more rapidly than the sealed ones? I think I feel safer to have all unsealed cells emptied.

USING PARTLY FILLED SECTIONS.

In this connection I want to caution the inexperienced against following to too great an extent the advice of Mr. Frank A. Eaton, GLEANINGS, page 131. A year ago I think I would have given just the same advice. In fact, in my book, "A Year Among the Bees," I speak of saving partly filled sections to use again. I have made considerable use of them, and I think generally to good advantage; but after last year's experience I shall not use them again unless it be a single one in a super. I had quite a number of sections partly filled, left over, and among them were some containing candied honey. These sections were filled, as friend Eaton suggests, very promptly, and when taken off I thought I had done a nice thing; but very soon they began leaking through the sealing, although kept in a good place, and none that commenced leaking could be sold as first-class honey. Contrary to friend Eaton's experience, and I think to my own previous experience, the honey in some of these sections was candied. This year I shall put on many sections that were partly filled, but the honey was all extracted last fall. I formerly put these partly built sections in the outer rows of the super, but further experience makes me prefer to put them in the center.

THE STING-TROWEL THEORY.

Not long ago I saw an item in a newspaper to the effect that "Naturalist Clarke" had discovered that the sting of the bee is used as a trowel, etc. This was stated in all seriousness; and if it is to pass

into general currency as a fact, and *if* it is not a fact, the sooner it is contradicted the better. When I first read the statement in friend Clarke's book I was somewhat startled, and didn't know whether to think there was some joke about it or whether a practice of the bees of thousands of years' continuance had just come to light. Just why the proof for any such belief has not been challenged before the communication of friend Savage (I think he is the first), I can not say. Possibly respect for the source whence it emanated. I hereby tender my apologies to friend Clarke for my silence hitherto, a silence of which I am by no means proud, as I do not know whether to attribute it more to cowardice or laziness. I don't believe there is any proof that bees ever work wax with their stings. On page 144 of GLEANINGS friend Clarke occupies about a page in reply to friend Savage's communication, yet I fail to find any thing in it to establish a belief that the sting is used as a trowel. If such a thing is true, has any one ever seen the operation? Surely many have watched bees in the operation of wax-working. During the honey harvest, bees are constantly working wax, and I have seen them at it many a time, but never with the sting. Thousands have probably seen the same thing, but I think no one has ever seen the sting used as a trowel. If they have, I think it has never appeared in print. This, it is true, is only negative proof against the theory; but in the absence of any positive proof on the other side, I think it counts for much.

In his article, friend Clarke makes use of Ernest's silence as so much testimony in favor of the sting-trowel theory. If Ernest has any shadow of proof of the truth of the theory, will he please let us have it? At any rate, will he please say whether he has or has not any evidence that bees work wax with their stings?

C. C. MILLER.

Marengo, Ill., May, 1887.

On page 20, in reply to D. F. Savage, after speaking of the mechanical structure of the sting, I said, "As to the office of the sting curing honey or tapping the cells, I have nothing to say, either pro or con." Friend M., this was, in fact, all I could say. I had never made any observations at the hive, to determine this question, aside from my microscopical observations, and was unable to find any literature bearing directly on the point. The only argument I can use in refutation of Clarke's theory of the bee-sting as a trowel is, that its mechanical construction (if my observations with the microscope are correct) would make it almost impossible. I once spent my whole vacation, of a week's time, in dissecting, studying, and mounting bee stings. I used a Bausch & Lomb microscope, with American lenses. I had at my disposal not only all the necessary dissecting-tools, but a 1-inch, $\frac{1}{2}$ -inch, $\frac{1}{4}$ -inch, $\frac{1}{8}$ -inch, and a $\frac{1}{16}$ -inch objective, and I am prepared to say that the bee-sting is in no respect like a trowel; and by watching its pumping motion under the microscope I could discover nothing in the working of the muscles that would lead me to believe that a bee could use it as a trowel. There is, however, nothing in the construction of the sting that would preclude the bees from puncturing the cells; and those who have had experience with the "business end" of a bee would not say that this is impossible. If our read-

ers should so request it, I will, during the winter months or when I have more time, take the specimens which I mounted during that week's vacation, stand over our engraver, and have him reproduce them upon the block for print.

In addition to the above remarks by Ernest, I would say that I have watched bees for hours through the glass of an observatory hive, and I have seen them build the cells, fill them with honey, and cap them over, but I never saw any movement that would indicate that the bee was ever in the habit of using the sting at all, or to indicate that he remembered he had a sting, while engaged in the business of capping over newly gathered honey, and I have seen them put on the last finishing touch.

A PLAN FOR MAKING ARTIFICIAL SWARMS.

ALSO SOMETHING ABOUT HOUSEHOLD CONVENIENCES.

IF Tom, Dick, and Harry (and two other fellows), all living in different places, would each give me a frame of black brood, covered with bees, could I unite them in an empty hive with a frame of Italian brood, with a capped queen-cell from my own hive, and thus form a good working colony?

I was just remarking, that I found it next to impossible to get honey now that tasted like that eaten twenty-five or thirty years ago on the old farm. Seeing the article about honey remaining in the hive to ripen giving it an improved flavor, suggests a possible explanation. Or is it because the honey eaten in those days was eaten while two little bare feet dangled under the table, while now I wear boots and walk with a cane, while one pair of hands that dished out that honey has rested under the snows of over twenty winters?

Relating to your suggestion about providing labor-saving machines for the housewife, let me say a word. Washing-machines are generally voted a nuisance. I had no faith in them. My mother-in-law tried an improved "Western Washer," of Jamestown, N. Y. When she used it a year she said it was a grand success. I then risked getting one for my wife. She also says it is a success. If you or your readers wish to try one of these machines, by all means get the number 3. It costs two dollars more, but it will wash bed-clothes. If we can find any thing to lighten poor tired women's work on washday, we should publish the good news. We also have an Empire clothes-wringer. They are double-gearred, and easily turned. There is continual complaint about this make of wringers getting out of order. It is the fault of the manipulator or washwoman. It is so easy to turn, that the operator will run sheets or table-cloths through on the same adjustment they use for towels and napkins, thus bursting out the rolls. By all means get the easy-running Empire make, then teach the girls how to use it. Now, do not think I am securing a free advertisement for any appliances. I am simply trying to encourage an effort to lighten and facilitate work. Instead of beating our eggs with a spoon we use a Dover egg-beater. Our butter is churned in about

twenty minutes with a Union churn from Tiffin, Ohio. The churn is worked with a crank. The operator can sit down and read GLEANINGS while making the cream fly for butter. Some years ago when I was a drug clerk I learned many useful things. I learned the value of Basilicon ointment (accented on the second syllable). It is good for burns, bruises, healing, boils, or sores of almost any kind. Once a lady had erysipelas on her arm. She used this, and the arm got well. Whether the ointment cured it or not, I could not say without further trial. It is good to keep in any house where there are children. It can be sold for about five cents an ounce. Perhaps it would help bee-stings. I never tried. It is not a quack medicine, but a recognized pharmaceutical preparation.

Pittsburgh, Pa., May, 1887. P. S. DILWORTH.
